The determination of insulation resistance and of faults during the working of electrical supply is a problem which has forced itself on the notice of every station manager, but is one which has often baffled him. Dr. O. Froelich has sent us, in English, a valuable article on this subject, but we have been unable until now to present the first instalment of it to our readers. The subject is readily handled by the mathematician or the arm-chair engineer, but Dr. Froelich clearly recognises the practical considerations of the problem, and the rather elaborate formulæ which will appear in our next issue should not cause needless alarm; the testing of submarine cables, as the author observes at the conclusion of the articles, was at one time regarded as "scientific humbug."

Prof. G. Forbes' suggestion that other correspondents should add to his list of useful formulæ has resulted in several communications, some new and some old. That such formulæ should be useful, in the sense implied by Prof. Forbes, they ought to be in an easily remembered form. Mr. Kingdon's rule, for example, contains a rather long row of 0's, and when the sectional area of a wire has to be measured in square inches, the application of this formula will be accompanied by a rather bewildering number of insignificant but important cyphers. A modification of this rule is that a wire of a sectional area of one-thousandth of a square inch runs 12½ feet to the ohm. Accurately, 12·66, or, at 95 per cent. conductivity, 12. In connection with this, a rule for the area

Hosted by Google

of a circle may be useful, since, if we have to look up the area of a wire in a table, we may as well look up the resistance. To find the area of a circle approximately, square the diameter and subtract one-fifth. For example—diameter 5, the square is 25, the square less one-fifth is 20; the true area being 19·6349, or 1·8 per cent. less. For greater exactness, therefore, subtract also 2 per cent.

Cable Interruptions and Repairs—

	Interrupted.	Repaired.
Senegal-Pernambuco	Dec. 26, 1892	Feb. 9, 1893.
Cayenne-Vizeu	Sept 24, 1892	—

The Engineering Exchange.—On Monday, the 30th ult., the Lord Mayor formally opened the Engineering Exchange in Billiter-street.

Lancaster.—The Town Council has resolved to apply for power to borrow £25,000 for the purpose of carrying out an electric lighting scheme.

Personal.—Mr. Emile Garcke, having accepted the appointment of managing director to the Electric Construction Corporation, has resigned his seat on the Board of the Brush Electrical Engineering Company.

Electricity on the Stage.—At the Comédie-Française a new drop-curtain, raised and lowered by electric motors, has been installed by the Edison Company, the current being derived from the Palais Royal Station.

St. Pancras.—At the last meeting of the St. Pancras Vestry, Mr. Sweet, Chairman of the Electricity Committee moved the adoption of the accounts for the year ended December 31st last. The motion was adopted unanimously.

Liquid Oxygen.—At the general monthly meeting of the members of the Royal Institution, held on Monday last, special thanks were returned for several donations, amounting in all to £110, for carrying on investigations on liquid oxygen.

Newcastle-upon-Tyne Electric Supply Company.—For the year ended December 31st last the units metered by this Company's meters were as follows:—Private consumers, 330,838; public lamps, 4,303; used at works, 11,687; total, 346,828.

Woolrich's Magneto-Electric Machine.—The Birmingham Corporation have granted, through the United States Commission, the loan of the historic Woolrich Magneto-Electric Machine to Messrs. J. E. Hartley and Son, of Birmingham, who will exhibit it at Chicago.

Cyclone Dust Collector.—We understand that Prof. V. Boys is not the inventor of the cyclone dust collector, as suggested in our last issue, but was engaged on the recent patent case in connection with the allegation that the Boys and Cunynghame steam trap was an anticipation of the above invention.

The St. Pancras Arc Light Pillars.—People in the Euston-road were alarmed one evening recently by an explosion. Some gas is stated to have accumulated in one of the arc lamp columns, and having ignited explosively, blew out the door to the switch chamber at the base. The light itself, however, was not affected.

Trans-Mediterranean Cable.—The steamer "Calabria," having on board the cable to be laid for the French Government between Marseilles and Tunis, arrived at Bizerta yesterday, having successfully accomplished the first part of the operation. Between Bizerta and Tunis, the junction will probably be effected in two days.

Westminster Electric Supply Corporation, Limited.—This Corporation give notice that, from March 31st next, the standard charge for electric energy will be reduced to 6d. per Board of Trade unit, with a sliding scale of rebate to clubs and other large consumers. For current supply for lifts and other motor power the charge is 5d. per unit.

Firth College, Sheffield.—A *conversazione* has just been held at this college to celebrate the completion of the additional building. The addition comprises new physical and biological laboratories, workshop, and class-rooms, and considerably increases the accommodation available for teaching purposes. The cost, £5,500, has been wholly defrayed by local subscriptions.

Patents in 1892.—The record of applications for patents in the United Kingdom during the past year shows that the increase noted annually since 1883 still continues. The number of applications in 1892 was 24,166, a total far exceeding that of any previous year, and greater by 1,278 than that of 1891. In the United States the annual number of applications for patents is about 40,000.

The Tudor Accumulator.—In the latest type of Tudor cell, the negative plate is a lead sheet, scored vertically, and the positive plate is composed of horizontal triangular strips, arranged in a series of vertical columns. Each plate rests on a glass block running across the cell underneath it, and secured at either end in a groove, the glass supports themselves resting on a strip of rubber running down each side of the cell.

The Adams Prize.—The Adams Prize, offered biennially and open to the competition of all persons who have at any time been admitted to a degree in the University of Cambridge, has been adjudged to Prof. J. H. Poynting, D.Sc., late Fellow of Trinity College. The subject of the essay is, "The Methods of Determining the Absolute and Relative Value of Gravitation and the Mean Density of the Earth." The prize was last awarded in 1883.

Bewdley.—At the last meeting of the Town Council a report was brought up from the Electric Lighting and Water Committee relative to the possibility of utilising the water of the Severn for the purpose of pumping water for the supply of the Borough, and for providing the electric light. Power was asked to incur a small expense for making further inquiries. There was considerable discussion on the subject, and ultimately the report of the Committee was adopted.

Ships' Electric Side Lights.—A memorandum having been received by the Admiralty from the Board of Trade stating that the tint of green in ships' side lights is affected when the lamps are lighted by electricity, the Portsmouth officers have ordered that, with a view of ascertaining whether the tint of green used in the naval service is suitable for navigating purposes, a report is to be forwarded through him to the Admiralty from each ship fitted with electric lanterns.

Electrical Bills in Parliament.—On Monday evening last private Bills, the progress of which was interrupted by the general election, were brought in and read a first and second time in accordance with the relief order of February 15th last. The Bills included the Baker-street and Waterloo Railway, City and South London Railway, Hampstead, St. Pancras, and Charing-cross Railway, London County Council (Subways), National Telephone Company, and Waterloo and City Railway.

The Distribution of Electric Energy.—In a recent issue we called attention, in the course of some remarks on a County Court decision, to the fact that no statutory "electric lighting" company bound itself to do more than supply "electric energy," a fact which, by itself, invalidated the argument that consumers' lamps were part of a company's plant. *L'Industrie Electrique* puts the matter very pithily. "The distribution of light," says our contemporary, "is, in the present state of our knowledge, theoretically possible, experimentally realisable, but commercially absurd."

Windsor.—The Windsor and Eton Electric Light Company are now supplying current to a few business premises. The mains are laid upon a system devised by Mr. T. Tomlinson, late chief engineer to Messrs. Gordon and Co., and described in our issue of December 2, 1892. The conductors are copper tubes, having a sectional area of 0·1 square inch, and they rest on porcelain insulators laid in a concrete trench, the trench being filled up with an asphalte composition. Over this strips of calico are placed to exclude dust or dirt, and then the whole is sealed in with concrete filled in up to the pavement.

The West End Street Railway (Boston).—The United States have been suffering from an unusually severe visitation

Hosted by Google

of snow lately, and the technical journals contain numerous reports of the manner in which the "electric cars" overcame all obstacles. In Boston the service of the West End Street Railway is said to have been maintained admirably. They had out 80 snow-ploughs and sweepers, each run by two 25 H.P. motors. About 160 miles of track had to be cleared. They were sent out the moment snow came on, with the result that not a single trip was lost.

The Hodgkins Fund.—On the subject of the Hodgkins Fund the following resolution has been passed by the managers of the Royal Institution:—"Having regard to the fact that the work of the Institution is devoted to the attainment of truth, and thereby constitutes in itself an investigation of the relations and co-relations existing between man and his Creator, resolved, that the income of the fund be devoted to that work, and that once in seven years a sum not exceeding 100 guineas be paid to some person, to be selected by the managers, for writing an essay showing how the work of this Institution has during the preceding period of seven years furthered the objects of the trust."

Obituary.—The death is announced of Mr. Alfred Carpmael, a member of the well-known firm of Wilson, Bristows and Carpmael, who act as honorary solicitors to the Institution of Electrical Engineers.——The death is also announced of Mr. George Mathews Whipple, superintendent of the Kew Observatory. Mr. Whipple was fifty years of age. He entered the Kew Observatory in 1858, and in 1862 became magnetic assistant. He was appointed superintendent of Kew Observatory in 1876, and for the past sixteen years he has contributed the results of his investigations to the Royal Meteorological Society. The magnetic part of the report of the committee of the Royal Society which met to discuss the Krakatoa eruption and the subsequent phenomena was written by him.

Derry.—At the last meeting of the Lighting Committee of the Corporation the following resolution was carried unanimously:—"That the sanction of the Local Government Board having been given to the application of the Corporation for a loan of £15,000 at 3½ per cent. interest, the principal repayable by equal instalments in twenty-five years, for the public lighting by electricity of the city, including the Waterside, it is resolved that such loan be accepted, and, in order to ascertain accurately the cost of the proposed scheme, that tenders be invited for the carrying out of the works in such form that contractors can tender for the whole or any part or parts of same, the erection of the buildings for the generating station to be confined to local contractors."

The Cable Ship "Amber."—A *Times* telegram, dated Zante, February 8th, says:—"The cable ship 'Amber,' belonging to the Eastern Telegraph Company, has arrived here, having been ordered hither from Egypt as soon as the news of the disastrous earthquakes in the island became known. Her officers and crew are now energetically assisting in alleviating the existing distress. A quantity of stores most needed by the inhabitants have already been landed from the vessel. Captain Greey, of the 'Amber,' has been received by King George, who expressed to him his gratitude to Sir John Pender, Sir James Anderson, and the other Directors of the Eastern Telegraph Company, for the help given in the hour of trial. His Majesty declared that he would never forget the energy which the English had shown in providing prompt relief for the distressed."

Electric Traction in Brussels.—A proposal is well advanced for providing Brussels with an underground electric railway similar to the South London line. The railway will be arranged similar to the Inner Circle railway, having eleven stations at the most important points of the City. No locomotives will be employed, but each train will consist of only one first and second-class composite bogie carriage, to carry forty passengers, with a compartment in front in which the electric traction gear will be arranged. It is proposed to run eleven such cars in each direction, and to work the traffic by the automatic electric block system, as adopted on the Liverpool electric railway. The lifts at each station will be operated by electric power. Messrs. Alexander Penney and Co. are the agents for the syndicate, and Mr. J. H. Greathead has been appointed engineer.

The First Swan Lamp.—On Wednesday morning last, at a quarter to 6, the premises of the Literary and Philosophical Society of Newcastle-on-Tyne were discovered to be in flames. The outbreak was first noticed by a telegraph clerk, who communicated by telephone with the fire brigade. The Society was founded in 1793, and the foundation stone of the present building, which cost £14,500, was laid by the Duke of Sussex in 1822. On Tuesday evening the centenary of the Society was celebrated by a *conversazione*. Half of the library of 35,000 volumes was completely destroyed, and the flames scorched all the books and the furniture which were not destroyed. The building was heated by hot-water pipes and lighted by electricity. The cause of the fire is not known. It was in this Society's rooms that on February 3, 1879, Mr. Swan showed to an audience of 600 to 800 persons the first carbon glow lamp running off a dynamo.

Fatal Electric Light Accident.—A dynamo tender named George Gifford, an *employé* of the Brighton and Hove Electric Light Company, met his death late on Sunday night last. It appears that the deceased went to the assistance of the electrician in charge, Mr. E. R. Maples, engaged in switching the load over to one dynamo, and that the deceased inadvertently put both his hands behind the base of one of the switch plugs, and was killed. At the inquest evidence was given to the effect that the deceased had been warned of the danger of doing what he did, and that he was a steady, competent, experienced man. Amongst the witnesses called was Mr. George Joseph Philpott, chief engineer to the Company, and Mr. William Lowrie. After deliberation, the jury returned a verdict of "Accidental death," and added a rider to the effect that the instruments ought to be more efficiently protected, the foreman remarking that it ought to be done, and done at once.

The London County Council and Technical Education.—The Report of the Technical Education of the London County Council, which was discussed by us in a leading article on January 27th, came up for adoption at the meeting of the Council on Tuesday last. The following addition to resolution No. 1, recommending the Council to exercise its powers under the Technical Instruction Acts, 1889-91 was carried:—"Provided that the City Livery Companies be invited to contribute for the same purpose a sum of not less than one-tenth of their corporate income as distinguished from their trust property." Resolution No. 2, recommending the formation of a composite body, to be called the Technical Education Board, to administer the funds, was agreed to by a large majority, notwithstanding that Mr. Tillett objected to such delegation of authority as being "antagonistic to democratic principles." The discussion was adjourned after acceptance of the third recommendation, that the Board should be appointed for a term of three years.

The Drehstrom at Dresden.—The administration of the Royal Saxon State Railways has decided on the construction of an electric central station to supply all the Dresden railway stations with light and power. From the various schemes submitted, that of Messrs. Siemens and Halske, slightly altered by Mr. Ulbricht, of Dresden, was adopted. This scheme proposed the use of the "drehstrom." On completion of the station, the output is to be 1,300 H.P. The installation will consist of five boilers, four engines, and the same number of "drehstrom" machines of 330 H.P., each running at a speed of 100 revolutions per minute. The station pressure of 120 volts is raised by transformers to 3,000 volts, and reduced again for use at the lamps and motors. The network stretches to places four miles distant, and feeds 600 arc lamps and over 3,000 glow lamps. The work has been divided between Messrs. Siemens and Halske and the Helios Company of Cologne, the former firm being responsible for the station, the motors, and the station transformers, while the latter company provide the mains and the lighting arrangements. This station will be the largest in existence working on the "drehstrom" principle.

The Telephone Tubes in the City.—At the last meeting of the Commissioners of Sewers the clerk read a letter from Mr.

Hosted by Google

H. S. Foster, M.P., pointing out that the City of London Electric Lighting Company would ask permission to break ground for the purpose of laying down tubes for telephonic purposes, the right of which he stated had been sold to the Pioneer Company, and then transferred to the new Telephone Company, and finally transferred to the National Telephone Company. Much serious dissatisfaction existed in the City in respect to the present charges for the use of the telephone, and it was intended therefore to establish a new company which would introduce a better and cheaper system. Mr. Foster also reminded the Commissioners that if they gave their permission to the application they would be giving also a monopoly to the National Telephone Company, and he hoped permission would be postponed. Mr. Morton, in moving that the subject should be referred to the Finance and Improvement Committee and the Streets Committee, said the citizens needed protection in the matter. This motion having been seconded, it was carried, the Remembrancer was instructed to oppose the National Telephone Company's Bill on the second reading.

Electric Smelting Patent Litigation in America.—The suit between the Pittsburg Reduction Company, of Pittsburg, Pa., and the Cowles Electric Smelting and Aluminium Company, of Lockport, N.Y. and Cleveland, Ohio, for infringement, was, says the *Electrical Engineer* of New York, decided in favour of the plaintiffs, on January 11th, by the United States Circuit Court for the Northern District of Ohio. The decision, says our New York contemporary, was a sweeping one, inasmuch as the Hall patent for the reduction of pure aluminium by electrolysis was sustained on every point. Mr. Hall's invention consists in the reduction of alumina by dissolving it in a fused mass of fluoride of aluminium, together with a fluoride of some other metal more electro-positive than aluminium, and precipitating the metallic aluminium from the dissolved alumina by means of electrolysis. The dissolving fluoride bath remains practically constant, and the process is a continuous one, for the reason that the ore is simply dumped into the bath, when the precipitation immediately begins, and the metal is either tapped out, or ladled out without any interruption whatever. In 1866, Mr. Hall had an interference suit with M. Heroult, owner of the large aluminium works, near Schaffhausen, on the Rhine. The suit lasted a year, and Mr. Hall was adjudged the prior inventor. The point then at issue was one of those raised in the present suit.

Exports of Telegraphic Apparatus.—The Board of Trade Returns, just published, enable a comparison to be made of our exports of telegraphic wires and apparatus connected therewith for the whole of last year in comparison with the two previous years. The figures are disappointing both for the month of December and for the twelve months. It will be seen from the table given below that the total value of our exports under this head for 1892 were less than £1,000,000, as compared with nearly £1,500,000 in 1891, and as compared with considerably over £1,500,000 in 1890. The percentage decrease last year was 36 as compared with 1891, and 43 as compared with 1890:—

—	1890.	1891.	1892.
First quarter	£324,670	£653,081	£96,079
Second quarter.....	397,042	331,449	579,756
Third quarter	210,280	342,106	124,605
Nine months.....	£931,992	£1,326,636	£800,440
October	£335,064	£38,167	31,198
November	246,378	25,143	39,993
December	88,829	44,927	38,439
Year	£1,602,205	£1,434,020	£910,070

It will be seen that the aggregate figures do not quite tally with the total monthly returns. This is owing to the fact of previous returns having been adjusted since their issue.

Belfast.—There seems to be a possible opening for electric traction in Belfast. The option of purchase by the Corporation of the whole tramway system matures in August next, and the new agreement which it is proposed to enter into appears to be exciting no little opposition in the town. The gist of the agreement which the tramway company, with the approval and assistance of the Corporation, are promoting in the form of a Bill is that the Corporation grants the Company a further lease of the streets of Belfast for fourteen years at a rent of £4,000 a year for the first seven years, and £5.000 a year for the second seven years of the term. Beyond that, says the *Northern Whig*, there seems to be no guarantee either for cheap fares, good service, or modern improvements. The traffic returns for the years 1887 and 1891 respectively show that totals were 7,638,191, and 16,393,426 — more than 100 per cent. increase—although the additional extent of lines opened during these four years was only $3\frac{3}{4}$ miles. The mileage of the system was $19\frac{1}{4}$ in 1891, as against $15\frac{1}{2}$ in 1887. Belfast, with $19\frac{1}{4}$ miles of tramway, carried nearly as many passengers in 1891 as did the Dublin United system with 33 miles. The Act promoted by the Company is not yet passed, says the *Northern Whig*, and as the result of the growing spirit of discontent, a combination of ratepayers has been formed to oppose it in Parliament. A considerable sum of money has already been subscribed to meet the costs of such a proceeding, and it is anticipated that there will be trouble before the contract becomes law. As the ratepayers appear to be interesting themselves in the subject, our Belfast contemporary proposes to publish a series of articles giving some of the results of inquiries and personal investigation.

The Forthcoming International Electrical Congress.—A meeting of the Advisory Council of the Chicago World's Congress of Electricians was held at the rooms of the American Institute of Electrical Engineers, New York, on January 17th. The following were present:—Dr. Elisha Gray (Chairman), Prof. William A. Anthony, Prof. Charles R. Cross, Dr. Louis Duncan, Dr. William Geyer, Mr. Carl Hering, Mr. George A. Hamilton, Prof. F. B. Crocker, Mr. A. E. Kennelly, Mr. T. D. Lockwood, Mr. T. C. Martin, Mr. George M. Phelps, Dr. M. I. Pupin, Mr. R. W. Pope, Prof. H. A. Rowland, and Mr. Herbert Laws Webb. It was resolved that the Electrical Congress should consist of two Chambers, of which the Legislative Chamber should decide on units, names of units, and standards, and consist solely of delegates named by their respective Governments. The following apportionment of delegates was made by a Committee whose report was adopted by the meeting. Great Britain 5, France 5, Germany 5, Austria-Hungary 5, United States 5, Belgium 3, Italy 3, Switzerland 3, Holland 2, Denmark 2, Norway and Sweden 2, Russia 2, Spain 2, Portugal 1, British North America 1, Australian Colonies 1, India 1, Japan 1, China 1, Mexico 1, Brazil 1, Chili 1, Peru 1, Argentine Republic 1, making a total of 55 official delegates. It was resolved to appoint a Committee on Invitations to consist of five members who are to select and recommend to the chairman the names of electricians, electrical engineers and others who shall be members of the Electrical Congress, the Committee to co-operate with the Foreign Committees. It was further resolved that in addition to invitations to deliberating and voting members of the Congress, a general intimation should be made through the journals or otherwise that the meetings will open to the public, for attending the proceedings, but not for taking part therein. A Committee on Programme and Papers was decided upon, whose duty it will be to invite, receive and consider Papers and other documents relating to the work to be done by the Congress. It was further resolved that it was to be the duty of this Committee to formulate a programme for the Congress. It was resolved that the reports of the English and American sub-committees which were received at the meeting should be referred to the Committee on Programme and Papers, and that the Committee should confer with the English Committee as fully as possible and with such other Foreign Committees as may be formed. It was resolved that the Electrical Congress of 1893 should last one week, beginning on August 21st. Finally it was resolved that the question of charging a fee for membership of the Congress, and fixing the amount of such fee should be referred to the Executive Committee.

THE DIFFUSION OF LIGHT.

BY W. E. SUMPNER, D.SC.

(*Continued from page 382.*)

Before describing the experiments by means of which the reflecting qualities of the various substances just referred to were measured, it may be well to give an exact meaning to certain terms which are often used in a somewhat vague way. By the *illumination* of a surface is meant the quantity of light incident on it per unit area of the surface. The *reflecting power* of a diffusing surface is the ratio of the amount of light reflected by it to the total amount of light incident upon it. The *candle-power* of a source of light in a particular direction is the intensity with which it radiates light in that direction, and in most cases varies with the path considered. The intensity of the light given off by a standard candle in the horizontal direction is taken as the unit of candle-power, and the illumination due to the horizontal rays of a candle at the distance of one foot may be taken as the unit illumination, and called a *candle-foot* The illumination due to a source of K candle-power at a distance of F feet is K/F^2 candle-feet. The *quantity of light* received by an area of A square feet placed perpendicular to the rays of light, and at a distance of F feet from the source of K candle-power is equal to the area multiplied by the illumination, and is, therefore,

$$K\frac{A}{F^2}$$

units of light. The ratio A/F^2 is called the solid angle subtended by the area A at the light, so that the quantity of light given out by a lamp of K candle-power within a solid angle Ω is $K\,\Omega$. If the lamp radiates light equally well in all directions, so that its candle-power is independent of the direction of the rays, the total quantity of light given out is $4\pi K$, since the solid angle subtended by a sphere at its centre is 4π, or 12·6. A light of 1 c.p. thus gives out 12·6 units of light, a fact which has been called "absurd" by some writers, who seem unable to distinguish between the ideas represented by the words "candle-power" and "quantity of light." There is, however, nothing more absurd about this statement than about the equivalent one that the area of a sphere of radius one foot is 4π square feet, and not simply one square foot. It might be for some reasons convenient to take as the unit quantity of light the total light given out by a source of 1 c.p. But the simplification so introduced would be apparent and not real; and it would be as undesirable to adopt this definition for the unit amount of light as it would be to use the area of a sphere of unit radius as the unit of area.

Besides candle-power, illumination, and quantity of light, there is one other term which it is necessary to use when considering the subject of diffusion. This term is the word *brightness*. A luminous surface may be said to have a brightness of one candle per square foot, when an area of one square foot of the surface acts like a lamp of 1 c.p. in the direction normal to the surface. If B is the brightness of a surface of area A the illumination produced by it at a distance, F, in the direction perpendicular to the surface is $B\,A/F^2$ or $B\,\Omega$ where Ω is the solid angle subtended by the area at the point at which the illumination is measured. The candle-power of a bright surface in directions inclined to the normal is found to vary as the cosine of the inclination of the ray to the normal, and from this fact it can be shown mathematically that the total quantity of light given off per unit area of a surface of brightness B is equal to πB.

It is this fact that renders it possible to measure the reflecting power of a diffusing surface. No instruments exist by means of which light can be measured as a quantity. But candle-power can be measured with a photometer, and the brightness, B, of a diffusing surface can be found by dividing its candle-power, measured in the normal direction, by the area of the surface. When B is once obtained, the total light reflected by the surface can be calculated from the formula $\pi B A$, where A is the area of the surface. To connect this with the reflecting power r of the surface we have the equation

$$\pi B = r I,$$

where I is the calculated illumination of the surface. This equation must hold, because I is by definition the amount of light incident upon the surface per unit area, and consequently $r I$ must be the amount reflected—that is, πB.

It is of some interest to compare the values of B for white paper under various conditions, such as frequently occur. Referring to some measurements made by Prof. L. Weber [*The Electrician*, Vol. XXV, p. 404], we find that when exposed to a summer sky the brightness of white paper is over 30 c.p. per square *inch*, or B = 4,300 c.p. per square foot. When illuminated by ordinary diffused daylight within a room, the value of B is much less, and may be obtained from the relation $\pi B = r I$. The value of I for ordinary daylight within interiors probably does not much exceed 20 candle feet; also r for white paper may be taken as 0·8. It follows that B is only $16/\pi$, or 5·1 candles per square foot. At night time a room is considered well lit if the illumination I is as much as 1 candle-foot, and in this case B is only 0·25. The illumination due to moonlight is about 0·025, and it follows that a piece of white paper exposed to the rays of the moon has a brightness of only 0·006 candle per square foot. The ratio of 4,300 to 0·006 is over 700,000, yet this large number represents the relative brightness of a piece of white paper when successively exposed to the rays of the sun and moon. What has been stated with reference to white paper applies, of course, equally to all diffusing surfaces, the brightness being simply proportional to the reflective power of the surface. Since this reflective power for most substances ranges between 20 and 80 per cent, it follows that the brightness of the walls of rooms (in candles per square foot) varies, as a rule, from 1 to 5 during the day, and during the night from 0·05 to 0·25. Even the blackest surfaces we know of are capable of reflecting a great deal of light. It appears from the results already referred to that black velvet, which is probably the worst of reflectors, is capable of shining with a brightness of over 6 c.p. per square foot when exposed to the summer sky at noon, and therefore can give off as much light as the same area of white paper when illuminated with diffused daylight such as ordinarily occurs within interiors.

The dazzling effect of a large white surface is well known, and Alpine climbers, and others who traverse fields of ice or snow, always protect their eyes from snow-blindness by using dark spectacles. The necessity for taking such precautions becomes evident on calculating the amout of light received by the eye from the snow-field. If B is the brightness of the field, and Ω the solid angle it subtends at the eye, the illumination at the surface of the eye due to the snow-field is $B\,\Omega$, and it will frequently happen that Ω is as much as a half a hemisphere, or π. But

$$\pi B = r I$$

where r is the reflecting power of the snow, and I is the illumination of the snow due to the sun's rays. The value of r for fresh snow is certainly over 80 per cent., and is more probably 90 per cent.; so that the illumination at the surface of the eye due to the snow is practically the same as if the eye were directed straight at the sun. The eye receives as much light in one case as in the other, and, indeed, it probably receives more light from the snow than it would from the sun, since in the latter case the eye would close up owing to the great brightness of the image of the sun on the surface of the retina. After an hour's exposure to a snow-field the eye has therefore received more light than if it had been looking at the sun for an equal time.

Measurements of Reflecting Power.

The following is a convenient method of measuring the reflective power of a diffusing surface, and was the one adopted in making most of the measurements recorded in Table I. The surface, whose reflecting power was required, was attached to a large screen of black velvet, O R, placed at one end O of a 3-metre photometer-bench O L (*see* Fig. 1), so as to be perpendicular to its length. Two lights were used, one being a Methven two-candle gas standard, placed at L; and the other a glow lamp K of about 20 c.p., placed at P. This second light was placed on the same slider as a Lummer-Brodhun photometer,* and just behind it. The photometer slider was

* For a description of this photometer see *The Electrician*, Vol. XXVI. p. 666.

Hosted by Google

moved along the bench till the illumination due to reflection from the surface O R was equalised by that caused by the direct rays of the Methven standard at L. In some cases both O P and O L were varied to get the adjustment.

If the distances O P and P L be equal to x and y respectively; if K and L respectively denote the candle-powers of the glow lamp and the Methven standard; and, finally, if A be the area of the diffusing surface on the screen O R, it can be shown that the reflecting power r is given by the equation

$$r = \frac{L}{K}\frac{x^2}{y^2}\left\{\frac{\pi x^2}{A} + 1{\cdot}75\right\}.$$

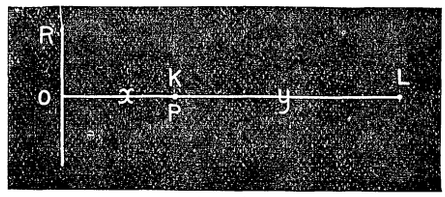

FIG. 1.

The area A should not be much longer in one direction than in the other. It should preferably be round, or nearly square, with its centre placed at O on the line of centres of the bench. The above formula is only true for surfaces which are purely diffusive. Some surfaces, such, for instance, as white enamelled iron, shine under the action of light, and reflect to some extent in accordance with the law of regular reflection. With such surfaces the value of r calculated from the above formula is found to vary with the value of x, and is too high. If r_1 is the proportion of the incident light which is diffused, and r_2 the proportion which is reflected according to the regular law of reflection, it can be shown that

$$\frac{L}{K}\frac{x^2}{y^2}\left\{\frac{\pi x^2}{A} + 1{\cdot}75\right\} = r_1 + \tfrac{1}{4}\left\{\frac{\pi x^2}{A} + 1{\cdot}75\right\} r_2.$$

The true reflecting power r is given by the equation

$$r = r_1 + r_2,$$

and, in order to obtain it, it is necessary to make experiments

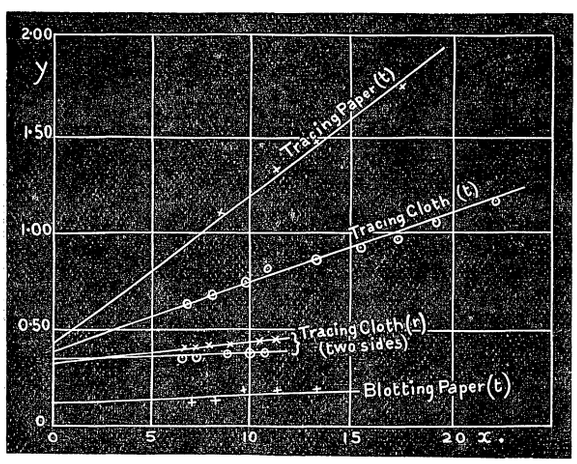

FIG. 2.—Value of $x = \frac{\pi x^2}{A} + 1{\cdot}75$.

Value of $y = \frac{L}{K}\frac{x^2}{y^2}\left\{\frac{\pi x^2}{A} + 1{\cdot}75\right\}$.

with various values of x, and to plot from the results a curve having for abscissæ the values of

$$X = \frac{\pi x^2}{A} + 1{\cdot}75,$$

and for ordinates the values of

$$Y = \frac{L}{K}\frac{x^2}{y^2}\left\{\frac{\pi x^2}{A} + 1{\cdot}75\right\}.$$

The equation between X and Y is that of a straight line

$$Y = r_1 + r_2\, X/4,$$

from which the values of r_1 and r_2 can be obtained. The value of $r = r_1 + r_2$ can be found by simply observing the value of Y, for which $X = 4$.

The observations referring to the reflecting power of tracing cloth, and plotted in Fig. 2, form an example of this method, and the observed values of the different quantities are given in Table II. This substance is the ordinary material used in drawing offices. It shines more on one side than on the other, but each side reflects a certain amount of light in accordance with the law of regular reflection. The values of x and y given in the table were the quantities actually observed. The values of X and $Y_{obs.}$ are calculated from x and y by means of the formulæ given above, and values of $Y_{calc.}$ are those given by the straight line

$$Y_{calc.} = 30{\cdot}9 + 4{\cdot}8\, X/4,$$

which most nearly goes through all the observed points.

Table II.—*Reflecting-Power of Tracing-Cloth (shiny side).*

A = 1,300. K = 12. L = 2. $r = 35{\cdot}7$. $Y_{calc.} = 30{\cdot}9 + 4{\cdot}8\, X/4$.

x	50	55	62·3	59·8	47·5	44·5
y	90	104·4	127·7	120·2	82·5	75·5
X	7·82	9·10	11·13	10·45	7·22	6·55
$Y_{obs.}$	40·4	41·8	44·1	43·2	39·6	38·6
$Y_{calc.}$	40·3	41·8	44·2	43·4	39·6	38·7

The four substances mentioned at the head of Table I. are common specimens of white diffusers. The first two—viz., blotting paper and cartridge paper—reflect a great deal of light and transmit very little. The two latter—tracing cloth and tracing paper—on the other hand, transmit a large portion of the light incident upon them, and reflect comparatively little. These surfaces were accordingly selected for the most careful measurements, and the results of the reflection tests are summarised in Table III.

(To be continued.)

ON THE DETERMINATION OF THE INSULATION RESISTANCE AND OF FAULTS IN ELECTRICAL PLANTS DURING THE WORKING.

BY DR. O. FROELICH.

At the present time the measurement of the insulation resistance and the detection of faults in electrical plants during working consists in taking the absolute potential of different points of the circuit, especially of the conductors in central stations, by means of incandescent lamps or galvanometers. Better methods are only given, to my knowledge, by Frisch (*Zeitschrift für Elektrotechnik*, 1889, p. 218) and by Dr. Hiecke (*Elektrotechnische Zeitschrift*, 1892, p. 534); the former gives a method of measuring the insulation, the latter shows how to find a heavy fault by measurements from the station. I describe here an almost complete set of measurements partly necessary, partly useful, taken during the working of continuous-current plants of every kind, a system which has been worked out and tried at the Berlin works of Messrs. Siemens and Halske.

Tests.—The problems to be solved are the following:—(1), Determination of the insulation; (2), Determination of situation and resistance of one fault in a simple circuit, the other existing faults being of higher order; (3), Determination of the resistances of several faults existing together, situations

Hosted by Google

of which are known (conductors of a central station); (4), Determination of the situation of a heavy fault in a complicated circuit (central station). All these tests have to be carried out during working without interfering with it. It will be shown that they can be carried out in quite a practical way. If one point of the circuit is connected to earth, as in telegraph circuits and in central stations, where the middle conductor is not insulated, it is impossible to determine insulation and faults in other parts of the circuit during working.

Properties of Faults.—If a circuit had absolutely perfect insulation—which none ever have, and cannot possibly have—the absolute potential of any point in it would be indefinite because the laws relative to potential refer only to differences of potential, not to absolute potential; in such a circuit very high or very low potentials could, therefore, occur. But if in one point of the circuit the potential is determined by any condition, all other potentials in the circuit are also determined.

If the circuit has only one fault at one point, viz., a communication to earth of any resistance, this point must assume the potential of the earth, that is to say, the zero potential. For, if it were not so, some electricity would flow to earth; but then there would be a continuous loss of electricity without return, which is impossible. If the circuit has two faults at different points, the same current goes from one point by earth to the other point; consequently, the potential of one point must be positive, that of the other negative, and the (absolute) potentials of the points are inversely as the resistances of the faults. If there are many small faults and one heavy one, the current in the latter is equal to the algebraic sum of the currents in the other ones; but the direction of the currents in the small faults can be different. If we determine the situation of the fault, supposing that there is only one fault, the calculated situation of the resultant fault will be near the heavy fault. If there are many small faults of about the same

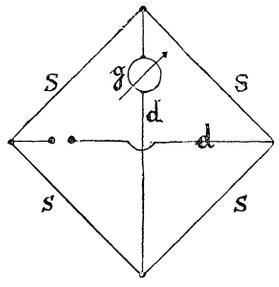

Diagram A.

order over the whole circuit, the position of the resultant fault will be near the middle of the circuit; in this case we only consider the sum of all faults or the insulation.

In theoretical deductions about faults it is often of advantage to introduce the conductivity, K, of the fault, instead of the resistance, F, of the fault; the conductivity is the reciprocal of the resistance: $k = 1/f$. The conductivity (K) of all the faults is the sum of the conductivities of the separate faults, and is equal to the reciprocal of F, the insulation resistance.

$$K = \Sigma k = \Sigma\, 1/f = 1/F.$$

Methods of Measurement.—The two methods chiefly employed are the interposing of galvanometers between points of the circuit and earth, and bridge measurements in various combinations. The first method presents two features. If the resistance of the galvanometer is great, the potentials in the circuit are scarcely altered by the interposition of the galvanometer; the deflection of the latter gives then the absolute potential of the point of the circuit in question. If the resistance of the galvanamoter is small, the insertion of the galvanometer is like the addition of a new fault of known resistance, effect of which upon the potentials in the circuit can be made use of for the measurement.

The bridge measurements are based on the Wheatstone Bridge generalised by the writer (*see Elek. Zeit.*, 1886, p. 483, and 1888, p. 137), the principle of which is that the known proportion existing between the sides s of the parallelogram (Diagram A) in case of equilibrium is still true if there are electromotive forces in all branches; but the equilibrium must be arranged so that by opening or closing or changing the resistance of one diagonal branch d, the current in the other diagonal branch d remains the same; not disappears, as in the common arrangement.

In the use of this method the following practical hints may be given:—The diagonal branches can ever be interchanged. Instead of the battery hitherto in use in one diagonal branch, we can also put any resistance. If the current in the galvanometer, caused by the electromotive forces in the other branches, is so strong that the needle goes hard over it is not necessary to neutralise this current by some battery, but it is easier to use magnets, viz., a strong one brought near in a direction perpendicular to the axis of the magnet until the needle goes over in the other direction, and a feeble one turning on a vertical axis above or below the needle, by which the needle is made to swing freely. Then the sensibility of the instrument is about the same as if no current went through it. If a telephone can be used instead of a galvanometer, the opening and closing of the other diagonal branch must be made in regular repetition by a contact wheel turned by hand, or by an electric motor; then a distinct sound is heard in the telephone, which is easily distinguished from any other sound, such as the note given out by the dynamo; for equilibrium the first sound must disappear on opening or closing the other diagonal branch.

In some bridge measurements given below, the arrangement of the circuits is not wholly that of the Wheatstone Bridge, but a more complicated one, and we only give the final formula used in the practical measurement.

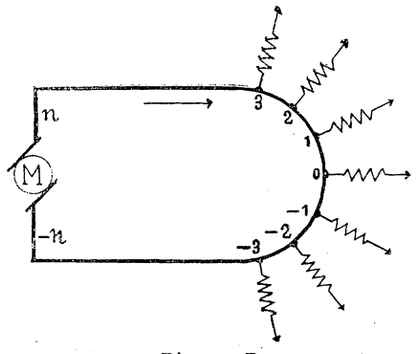

Diagram B.

Measurement of the Insulation.

Let us begin with a theoretical consideration. In the simple circuit (Diagram B), the external circuit between the poles of the machine be divided into $2n$ parts of equal resistance, with a fault between each two contiguous parts. Let us suppose that the difference of potential between the ends of each part be δ; to fulfil this supposition, the resistances of the faults cannot be very small, but in practice the supposition is almost always fulfilled. Let the middle point be 0; let the points between 0 and the positive pole be 1, 2, 3 . . . n, and the other points be $-1, -2, -3$ . . . $-n$. The resistance of the fault attached to the point m may be denoted by f_m, the conductivity of this fault by $k_m = 1/f_m$; the conductivity of all faults is

$$K = \sum_{+n}^{+n} k_m = \sum_{-n}^{-n} 1/f_m.$$

The currents of the faults we take positive in the direction to earth, and denote them by: $i_0, i_1, i_2 \ldots, i_{-1}, i_{-2} \ldots$ The potentials at the starting points by: $P_0, P_1, P_2 \ldots, P_{-1}, P_{-2} \ldots$

We have the equations

$$\sum_{-n}^{+n} i_m = 0$$

$$-i_0 f_0 + i_1 f_1 = \delta \qquad -i_0 f_0 + i_{-1} f_{-1} = -\delta$$
$$-i_1 f_1 + i_2 f_2 = \delta \qquad -i_{-1} f_{-1} + i_{-2} f_{-2} = -\delta,$$
$$\&c. \qquad\qquad \&c.$$

Hosted by Google

Resolving these equations we find

$$P_0 = \delta/K \{ -k_1 - 2k_2 - \ldots - nk_n + k_{-1} + 2k_{-2} + \ldots + nk_n \},$$

or $P_0 = \delta\, h/K$, where

$$h = -k_1 - 2k_2 - \ldots - nk_n + k_{-1} + 2k_{-2} + \ldots + nk_{-n}.$$

The other potentials are deduced from P_0 by

$$P_1 = P_0 + \delta_1,\ P_2 = P_0 + 2\,\delta, \text{ \&c.}$$
$$P_{-1} = P_0 - \delta_1,\ P_{-2} = P_0 - 2\delta, \text{ \&c.}$$

If we put a galvanometer of resistance g between the point m and earth, the resistance between m and earth is diminished, and instead of $1/f_m$ we must put $1/f_m + 1/g$. Then the potential at the point 0 will be

$$P'_0 = \delta\,(h - m/g)/(K + 1/g),$$

and all potentials are augmented by $P'_0 - P_0$.

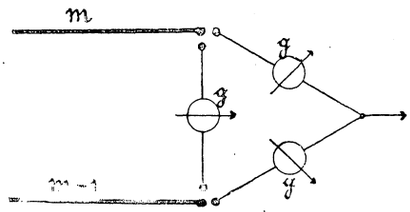

FIG. 1.

It follows that the potential of the middle point in the external circuit of any electrical plant is zero, if the sum $k_1 + 2k_2 + \ldots + nk_n$ on the positive side is equal to the like sum on the negative side, and that the effect of a fault of a certain resistance on the potential of the middie point is the greater, the longer the distance between the place of the fault and the middle point.

From the formulæ given the measurements of the insulation, which we give below, can be easily understood.

Method 1. (Fig. 1. Frisch).—Herr Frisch inserts a galvanometer first between one main conductor of a central station and earth, then between a neighbouring main conductor and earth, finally between the two conductors; by the three deflections so obtained the resistance of the insulation can be determined.

If the galvanometer lies between m and earth, its deflection in volts will be

$$P'_m = \delta\,(h - m/g)/(K + 1/g) + m\,\delta;$$

if the galvanometer lies between $m - 1$ and earth,

$$P'_{m-1} = \delta\,(h - (m-1)/g)/(K + 1/g) + (m-1)\,\delta;$$

if it lies between the two conductors, it gives δ.

Thence, it follows that

$$\left.\begin{aligned} K &= 1/g\,[P'_m - P'_{m-1}]/[\delta - (P'_m - P'_{m-1})] \\ F = 1/K &= -g + g\,\delta/(P'_m - P'_{m-1}) \end{aligned}\right\} \quad . \quad (1)$$

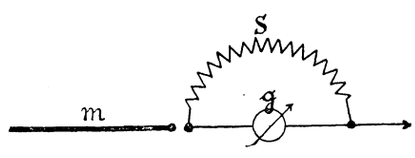

FIG. 2.

Method 2. (Fig. 2. Shunt Method.)—The insulation can also be measured by putting the galvanometer between one main conductor [point m] and earth, and varying the resistance of the galvanometer, viz., by measuring with and without the shunt s. Then we need only to take two deflections; and, if we vary the resistance of the shunt so that the second deflections is a certain definite part of the first one, we need only the resistance of the shunt. If the instrument is inserted between the point m and earth, the potential of the middle point will be

$$P'_0 = \delta\,(h - m/g)/(K + 1/g);$$

If we add the shunt s, the potential of 0 will be

$$P''_0 = \delta\,(h - m/g - m/s)/(K + 1/g + 1/s).$$

Thence we deduce

$$K = -1/g + 1/s(P''_0 + m\delta)/(P'_0 - P''_0)$$
$$= -1/g + 1/s(P''_m)/(P'_m - P''_m) \quad . \quad (2)$$

where P'_m and P''_m are the two observed deflections.

If the shunt can be varied, we arrange it so, that the second deflection is half of the first or $P''_m = 1/2P'_m$; then we have

$$K = 1/F = -1/g + 1/s \quad . \quad . \quad . \quad . \quad (2a)$$

where F is the resistance of the insulation.

If the galvanometer is very sensitive, we must add resistances to it to get a suitable deflection; the resistance g will be great and $1/g$ can be neglected. If, then, the second deflection is one-half of the first one, we have simply

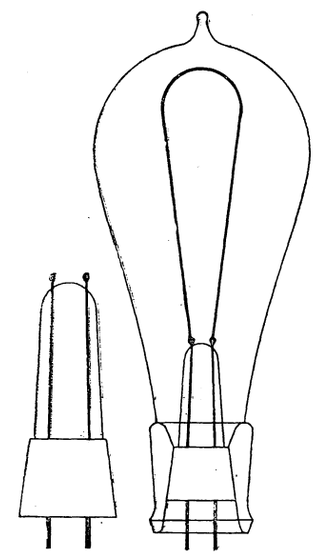
$$K = 1/s \text{ and } F = s \quad . \quad . \quad . \quad . \quad (2b)$$

viz., the resistance of the insulation is equal to that of the shunt. We see that by this method we need no calculation, but only a reading of the resistance inserted in a box.

(To be continued.)

THE NEW WESTINGHOUSE LAMP.

The new Westinghouse lamp, concerning which there has been so much speculation, has at length been exhibited to a chosen few at Pittsburg. The accompanying illustration from the New York *Electrical World*, represents the "preferred" form, and presumably the one which is about to be put upon the market.



The Westinghouse Separable Lamp and Stopper.

It was hinted some time ago that the filament, instead of being "sealed in" the glass globe by fusion in the usual way, was mounted on a glass stopper ground to fit the neck of the globe, into which it was secured by a cement. From the description now given, and by reference to the illustration, we are able to see how this is carried out. The neck of the globe is thickened both on the outside and inside, so that there is a considerable mass of glass at that end. The opening is conical in shape, and ground to receive the stopper, which is shown separately in the illustration. The stopper is a solid piece of glass, cast around the leading-in wires, and is ground to fit the neck of the globe. The leading-in wires are iron—not platinum. When the filament has been attached to the leading-in wires, the stopper is covered on its bearing surface with a varnish or cement, and is tightly pushed into its seat in the neck of the lamp. The lamp is exhausted at its upper end as usual. During exhaustion nitrogen gas is from time to time introduced and withdrawn again, for the purpose of entirely removing the least traces of atmospheric

Hosted by Google

oxygen. The exhaustion is, however, believed to be as perfect as it can be made.

The makers of the lamp say that it does not infringe the Edison patents. It has, in fact, been specially designed with that object. Whether that end has been achieved or not will probably be a matter for the American Law Courts to decide. It is difficult to see wherein the necessary difference lies. It surely cannot be that the filament is not enclosed in a receiver made entirely of glass. The globe is entirely composed of glass, and so is the stopper, though, to be sure there is a thin partition of varnish between the two. The first reports about the lamp stated that there was to be no vacuum, or at all events only a partial one. This, however, appears to be a mistake, for although nitrogen is said to be introduced into the lamp while pumping, it is all pumped out again as far as possible. The only other difference is in the use of iron wires instead of platinum. With all its differences then, the new lamp is still a combination of a carbon filament within a receiver of glass from which the air has been exhausted.

Now, apart from patents, there are several points in connection with the manufacture of such a lamp which call for attention. In the first place, can it be made for the same price as an ordinary lamp? It would certainly seem that it would cost considerable more. There is a great deal more glass in the globe. It is probably much thicker all over than in ordinary lamps, and there appears to be some difficulty in sealing it to the thick neck. Then there is the stopper to be made. The inside of the neck must be ground, the stopper must be ground, and then the two must be ground together. All this has to be done as against the usual simple process of sealing in with the blow-pipe. It may be claimed that there is a gain in the use of iron leading-in wires instead of platinum. This part of the invention was probably made at the time when platinum stood at a high price. The amount of extra labour required in the new lamp must, however, more than swamp the gain here. The amount of platinum really required in a lamp is very small, as may be seen in the ordinary Edison-Swan lamps. It takes very little labour to cost as much as this with platinum at its present price. Again, the introduction of nitrogen into the lamp during exhaustion must add to the cost, not only by the cost of the nitrogen and applying it, but in the time taken to exhaust the lamp. If, as is stated, nitrogen is introduced several times during exhaustion, the exhaustion is of course thrown back each time, and has to begin again. What the advantage of this process is, is not very apparent. It is said to be in order that the residual gas shall be nitrogen instead of atmospheric air. It is, however, open to doubt whether in an ordinary lamp the residual vacuum contains any uncombined oxygen. It is probably chiefly composed of gases given off by the filament when under current. It is certain that some particular gas is often present and may be detected by its smell when a lamp is opened.

One advantage claimed for the new lamp is that the bulb and stopper can be used again and again, and a considerable sum will be allowed by the makers for returned used-up lamps. This in itself is no doubt an advantage; but whether it will work in practice is another matter. It is said that the stopper can be easily removed. To do this the lamp is warmed, and the cement softens, the stopper can then be drawn out after the air has first been let in at the other end. If the cement softens by warming, is there not therefore a danger of its softening by the heat of the lamp itself and so losing the vacuum? Even if this is all satisfactory and the stopper can be removed at will, the inside of the bulb has to be cleaned. This is a troublesome process. Before the stopper can be drawn, the air must be let in by cutting off the tip of the nipple at the top of the lamp. For re-pumping the lamp a glass tube must be fused on to this end. This is not always a successful operation, as the globe is apt to crack at the place where the former tube was joined on. The danger of cracking will be greater each time the operation is performed.

It also remains to be proved whether the iron wire is satisfactory for the purpose of leading-in wires. Iron has a greater coefficient of expansion than glass. The glass in a molten state is cast around the iron wires, and it may be in close and air-tight contact with the wires at the temperature of solidification. But as it cools the wires will contract more than the glass, and will tend to shrink away from it. Consequently, it is highly probably that air may slowly leak into the lamp between the wires and the glass. Whether it actually does so or not trial only will show.

One thing is not mentioned in the description, namely, the method of joining the filament to the wires. Probably this joint is made with a carbon paste. It is difficult, if not impossible, to make the ordinary deposited carbon joint upon iron, because iron will not stand the temperature to which it must be heated in order to obtain a good deposit. There is another point to be considered. In order to obtain a good vacuum it is necessary that the lamps be strongly heated while being pumped. Now this appears to be impracticable in the case of this lamp for two reasons. Firstly, owing to the thickness of the glass at the stopper end, it would be liable to crack, especially round the sharp shoulder shown in the illustration. Secondly, the stopper cement melts if heated. It is probably on this account that it has been found necessary to use nitrogen. As the vacuum cannot be made nearly so perfect as in lamps heated during exhaustion, it is thought better that the residual gas should be nitrogen. This is a point which would tell somewhat against the lamp, because with such a vacuum the glass will get very hot.

All things considered, it appears highly improbable that this lamp will be able to compete with lamps made in the ordinary way.

MEETINGS OF SCIENTIFIC SOCIETIES, &c.

(TO-DAY) FRIDAY, February 10th.

PHYSICAL SOCIETY.

5 p.m. Annual General Meeting. After which the following Papers will be read: (1) "Recent Determinations of Molecular Refraction and Dispersion," by Dr. J. H. Gladstone, F.R.S.; (2) "The Separation and Striation of Gases," by E. C. C. Baly.

INSTITUTION OF CIVIL ENGINEERS.

7 30 p.m. Students' Meeting. Paper to be read: "Long Shoot Dredgers—their Design and Mode of Working," by H. Calder Löbnitz, Stud.Inst.C.E

SOCIETY OF ARTS.

8 p.m. Howard Lecture (5): "The Development and Transmission of Power from Central Stations," by Prof. W. Cawthorne Unwin, F.R.S.

JUNIOR ENGINEERING SOCIETY.

8 p.m. Meeting at the Westminster Palace Hotel. Paper to be read: "The Application of Small-power Electric-motors," by Douglas Heap and Arthur Heap.

ROYAL INSTITUTION.

9 p.m. Evening Discourse: "Some Associated Organisms," by Prof. Charles Stewart, Pres.L.S.

MONDAY, February 13th.

SOCIETY OF ARTS.

8 p.m. Cantor Lecture (3): "The Practical Measurement of Alternating Electric Currents," by Dr. J. A. Fleming, F.R.S.

TUESDAY, February 14th.

INSTITUTION OF CIVIL ENGINEERS.

8 p.m. Ordinary Meeting. Paper to be read with a view to discussion: "Electrical Railways," by Dr. Edward Hopkinson, M.A.

WEDNESDAY, February 15th.

ROYAL METEOROLOGICAL SOCIETY.

7 p.m. Ordinary Meeting at the Institution of Civil Engineers. Papers to be read: (1) "Report on the Phenological Observations for 1892," by Edward Mawley, F.R.Met.Soc.; (2) "Relation between the Duration of Sunshine, the Amount of Cloud, and the Height of the Barometer," by William Ellis, F.R.A.S.; (3) "Winter Temperatures on Mountain Summits," by W. Piffe Brown.

OLD STUDENTS' ASSOCIATION.

7.30 p.m. Meeting at Finsbury Technical College. Paper to be read and discussed: "The Series Method of Teaching Foreign Languages, and its Application to the Technical Professions," by Howard Swan.

SOCIETY OF ARTS.

8 p.m. Ordinary Meeting. Paper to be read: "The Detection and Estimation of Small Proportions of Inflammable Gas or Vapour in Air," by Prof. Frank Clowes, D.Sc.

FRIDAY, February 17th

INSTITUTION OF ELECTRICAL ENGINEERS

8 p.m. Students' Meeting. Paper to be read: "Cost of Private Installations," by W. L. Bayley.

THE LEEDS ELECTRIC TRAMWAY CASE.

The judgment given by Mr. JUSTICE KEKEWICH in the action brought by the National Telephone Company against Mr. GRAFF BAKER for disturbing their Leeds telephone service by the working of his electric cars is a satisfactory termination to the first skirmish between telephony and electric traction. To criticise Mr. JUSTICE KEKEWICH'S law is beyond our province and beyond our competence; from a lawyer's point of view it may not, perhaps, be unexceptional.

In delivering judgment, the learned judge skilfully concealed his final decision until he had thoroughly imbued the defeated side with the idea that they were the victors. Then, in a single sentence, the tables were turned. A marked contrast to Mr. JUSTICE ROMER'S mode of procedure in his three-wire judgment, in which the suspense of the audience was terminated in less than a minute. There was, said Mr. JUSTICE KEKEWICH, no question but that each party to the action was lawfully exercising undoubted rights. There was, moreover, no question but that the working of the Roundhay Park cars interfered to a very serious degree with the neighbouring telephone circuits; indeed, so serious was the telephonic disturbance that the remedy would have been by injunction rather than by damages—had any legal remedy existed. The real and only issue, however, was whether the nuisance was actionable. Referring then to the American cases, Mr. JUSTICE KEKEWICH said he had studied them with deep interest, especially the decision in the case of "Cumberland Telephone and Telegraph Company *v.* United Electric Railway," and he would not have hesitated to allow his own conclusion to have been guided by the powerful arguments there set forth, but for the fact that the principle of "Fletcher *v.* Rylands" was not fully recognised in America, whilst, in his opinion, the principle *was* applicable to the action in hand. The principle of "Fletcher *v.* Rylands" epitomised appears to amount to this: That where the owner of land, without wilfulness or negligence, uses his land in the ordinary manner of its use, he is not liable, should mischief thereby be occasioned, to his neighbour, but if he brings upon his land anything which would not

Hosted by Google

naturally come upon it, and which is in itself dangerous and may become mischievous if not kept under proper control, he will be liable in damages for any mischief thereby occasioned, even though he may act without personal wilfulness or negligence. It may be remarked that in this action the Plaintiffs practically abandoned the question of disturbance by conduction, their case being that the trouble arose from induction. The defences raised in the present action were numerous, but the principle arguments were :—First, that owing to the extraordinary delicacy and sensitiveness of telephonic instruments, and to the fact that the use of the earth return furnished imperfect and unsatisfactory results, such use was not an ordinary or *reasonable* use of property, and that therefore any interference with it did not amount to a nuisance. Secondly, it was argued that the National Company could obviate all disturbances by the adoption of metallic circuits; and thirdly, it was contended that Mr. Graff Baker was engaged in the lawful exercise of statutory powers, and must, therefore, be held free from blame for the injury done to the plaintiffs' property. As to the first plea, Mr. Justice Kekewich decided that all he had to consider was whether the use was a *lawful* use, and that if any distinction was to be taken between electrical currents and other forces, that distinction must be made by a higher tribunal. On the second plea, the Court held that the National Telephone Company could not be obliged to double its wires, nor, for matter of that, could Mr. Graff Baker be forced to keep his system constantly up to date by continually adopting "the last inventions of ever changing, ever advancing scientific discovery," the single wire overhead trolley method of traction being, in the judge's opinion, "on the whole, the best which practical science has yet discovered." On the other hand, the third contention of the defendants was considered good law, and judgment was therefore given in favour of Mr. Graff Baker, the licensee of the Leeds Corporation.

At first glance the principle upon which this decision is based appears to be of general application, and the judgment consequently one of the most momentous in the history of the electrical industry. Are not all tramways worked under an Act of Parliament, and before electricity can be employed must not a definite clause to that effect exist? It has, however, to be remembered that for several years past the telephone interest has succeeded in getting a most objectionable paragraph, known as the Birkenhead clause, inserted in most Acts having reference to electric lighting or traction. Since this clause was adopted at the time as a standard one to be made use of in all similar cases, it may not be amiss to quote it in full as it was accepted in July, 1890, by a Select Committee of the House of Commons, presided over by Mr. Stansfield :—"The Undertakers shall construct their mains and other works of all descriptions and shall work their undertakings in all respects so as not injuriously to affect the working of any existing electric circuits from time to time used or intended to be used for the purpose of telegraphic, telephonic or electric signalling communication, or the currents in such circuits, and shall use every reasonable means in the construction of their mains and other works of all descriptions in the working of their undertaking to prevent injurious affection, whether by induction or otherwise, to any electric circuits used or intended to be used for the purpose aforesaid, *whether existing at the time of the construction of such mains or other works or not.*" With a protecting proviso of this sweeping character snugly ensconced in numerous Tramway Acts—and likely, unless nipped in the bud, to continue to blossom forth in the same soil, season after season—the National Telephone Company can afford to regard its recent rebuff in a Court of First Instance with comparative equanimity. It has the power of the purse, and who can tell what may happen on Appeal or in the Lords?

On closer inspection, therefore, it would seem as if the victory of the tractionists in Chancery Court IV. were a Pyrrhic victory after all, and that so far as the Leeds cars are concerned it would be well to avoid further legal conflicts by a timely compromise, not prejudicing future action in other cases. The place to give effective battle is not in the Law Courts, but in the Legislature. The one-sided clause quoted above should be fought in Committee until it is mended or ended. By all means give the telephones a reasonable measure of protection. We have no desire to see careless work anywhere. The protection, however, should be reciprocal. It is an axiom in strategy that much may be done with a small force against a larger one by beating the scattered army corps in detail. In the present instance the telephone interest is not only the stronger, but it is better organised. The electric traction industry is being attacked in detail, and will inevitably be beaten unless an assault on any one of its members is deemed a menace to the industry as a whole. In other words, victory will ultimately be with the National Telephone Company unless their opponents combine together, no longer allowing a single concern to bear the burden and heat of the day, in the hope that those who stand aside may reap the reward properly due only to those who do the fighting and pay the piper. If an association were formed, a permanent guard could be kept upon the *fons et origo malorum*, the Legislature, and it might then be good tactics to continue the struggle in the Law Courts as well. What is the Traction and Telephone Committee of the Electrial Trade Section of the London Chamber of Commerce doing? This clause has been brought before them more than once, and they have been warned of its inevitable results on more than one occasion. The spirit of compromise is altogether admirable—within limits. Give and take is the very life of negotiation. There need be no fear that the telephone interest will refrain from taking; the danger is that the traction interest may leave itself with nothing to give. Action too long delayed loses the name of action.

OBITUARY.

JAMES EDWARD HENRY GORDON.

We regret to announce the death of Mr. J. E. H. Gordon. On Friday last he was riding near Thornton Heath, when the horse bolted, and, in turning a corner, threw him on to an asphalte pavement. He died an hour after his admission to the Croydon Hospital from extensive fracture of the skull. He was particularly fond of riding, and was considered to be an experienced and daring horseman.

Although prominent of late as an energetic contractor for the erection of electric supply stations in England and Ireland, Mr. Gordon's earlier work was perhaps the more important, and of this, the building of his large dynamos was one of the most remarkable examples, judged, of course, with reference to the time, and not compared with the practice of to-day. Mr. Gordon was born in 1852, and was educated at Eton and Cambridge, with a short interval at King's College, London. He took his degree in mathematics in 1875, and studied for a year or two at the Cavendish Laboratory under Clerk Maxwell. He afterwards set up a laboratory at Pixholme, near Dorking, at the house of his father, the late Dr. J. A. Gordon, F.R.S., Physician to the London Hospital. Here he conducted researches which were the development of his work at Cambridge, and which were published in the *Philosophical Transactions* of the Royal Society in 1877 and 1879. Amongst these were an investigation of the electro-magnetic rotation of

Hosted by Google

polarised light carried out under Clerk Maxwell's direction. The abstract of this Paper was published in *Proc.* Roy. Soc., June, 1875, rather more than a year before M. Henri Becquerel's memoir on the same subject. In 1878, Mr. Spottiswoode's year of presidency, Mr. Gordon became assistant secretary to the British Association, a post which he held for two years. At the Dublin meeting of this Association he gave an account of his investigation of sparking distances in air at different pressures. The experiment is described in *Phil. Mag.*, September, 1878. An elaborate research on the specific inductive capacity of solid and liquid dielectrics was published in *Phil. Trans.*, 1879. The apparatus, which was of considerable complexity, included a high-speed contact breaker, the invention of Mr. Gordon; it consisted of a toothed wheel, turned by an electric motor at 100 revolutions per second, and interrupting the current 6,000 times a second. His first series of experiments on dielectrics was made in 1877. In 1879 Mr. Gordon delivered four lectures at the Royal Institution on "Electrostatic Induction." These were published as a small book.

In 1880 he published a "A Physical Treatise on Electricity and Magnetism," a work which is now in its third edition and which has been published also in America and France. This book contains excellent accounts of the works of Boltzmann and others on specific inductive capacity, of terrestial magnetism and the instruments used for measuring it, of the B.A. determination of the ohm in 1863, Prof. Adams' work on equipotential lines and lines of flow, the researches of Spottiswoode, Moulton and De la Rue on discharges in vacua, and, besides other digests of Papers which otherwise are difficult of access, and his work contains five chapters on electro-optics. In 1879 and 1880 he was busily employed in experimenting on a platinum-iridium lamp, and on hearing that a discovery of iridium had been made in America, he is said to have called for a quotation for a supply of a ton of this metal. He had three patents for iridium amps.

In 1881 he was appointed one of the thirty-one English delegates to the Electrical Exhibition in Paris, and in the following year he built his first large alternate current dynamo at the Greenwich works of the Telegraph Construction and Maintenance Company. This machine was described in *The Electrician*, Vol. IX., p. 365. It was undoubtedly before its time, and cannot be said to have been a success, but it is of interest as being the first example of a large slow-speed dynamo. The 32-field magnets were mounted on a rotating wheel, 8ft. 9in. in diameter, and the stationary armature coils were coupled for any desired voltage; transformers were not in existence at that time. In 1884 he published his "Practical Treatise on Electric Lighting," in which a good account of the early manufacture of glow lamps is given. An instrument for measuring the strength of magnetic fields is described; this consisted of a coil which could be rotated through a right angle and caused to fly back suddenly by means of a spring; a modification for measuring the field between the magnet and the armature of a dynamo is also described. He predicted in this work that meters would probably be constructed with a snail cam, and an arm actuated by clockwork at intervals would strike the cam, and record the total length of all its journeys. Some four or five meters have since been constructed on this principle by other inventors. In this book the following curious chapter occurs:—

CHAPTER XIX.

Central Station Lighting.

I had intended to write a long chapter with the above heading, but, for various reasons, I am not yet prepared to do so. I have, however, left in the heading for the convenience of inserting such a chapter in a future edition of this book, should one ever be required.

With his varied experience of different systems, Mr. Gordon, if he had lived, could have written, not only a long chapter, but a most interesting book on this subject.

Nothing further besides a few experiments was done with his dynamo, which was protected by two patents, until 1884, when he designed the then largest central station, for lighting Paddington Station, offices, hotel, &c. The three dynamos, each weighing 45 tons, and having magnet wheels of 9ft. 8in. in diameter, while not large compared with modern machines (the two large Ferranti dynamos at Deptford having armatures 13ft. in diameter), attracted great attention at the time, as, indeed, did the many ingenious devices which were employed at this station. The Paddington plant was started on April 21, 1886.

In less than a year Mr. Gordon had turned his attention to continuous currents with secondary batteries for use at a station in Whitehall; and in the course of the discussion in February, 1888, on Mr. Kapp's Paper on "Alternate-current Transformers" at the Society of Telegraph Engineers and Electricians, he said that he had lately, even at the expense of abandoning every patent that he held, been so far convinced of the superiority of the method of distribution given by storage batteries that he felt compelled to abandon what had been identified as his own system. But with the impetuosity which was so marked a trait in his character, he proposed to run dynamos at full load for 12 hours, or for "24 hours, which may, in some circumstances, be advisable." It was not long before he had found out that batteries did not afford the storage for which he had hoped. It was at the close of this speech that, after alluding to different methods of distribution, he deprecated the then prevalent "system of distributing electricity from house to house by means of circulars in halfpenny wrappers."

The Whitehall Station becoming the nucleus of the present Metropolitan Electric Supply Company, Mr. Gordon became associated with the design of several new stations, being one of the original Directors of as well as Engineer to this Company. About a year later, in the autumn of 1889, he severed part of his connection with the Metropolitan Company and commenced business as a consulting engineer, and in the summer of 1890 taking Mr. W. J. Rivington into partnership, his restless activity found ample scope in the tempting occupation of erecting complete central stations and distributing systems at Carlow, Larne, Bray, Sydenham and Windsor, and his sad death occurred just at the time when, owing to the large expenditure of capital involved in such work, his business was embarrassed; and his career was cut short just when his energies were needed to pull through the difficulties which surrounded it.

F. VAN RYSSELBERGHE.

It is with deep regret that we record the death of the eminent Belgian electrician, M. Van Rysselberghe.

M. Van Rysselberghe was born at Ghent on August 25, 1846, and at the time of his decease was Consulting Engineer to the Telegraph Department of the Belgian Government; Professor of Electrotechnics at the University of Ghent; Chevalier of the Legion of Honour and of the Order of Leopold. Having mainly completed his education by his own exertions, M. Van Rysselberghe was, in 1865, appointed Professor of Nautical Astronomy at Ostend, where he invented the Maréeographe, for recording the rise and fall of the tide, and the Météorographe, for registering atmospheric changes. Having acted as hydrographical engineer, charged with preparing a chart of the Scheldt, he was in 1887 attached, as meteorologist, to the Royal Observatory at Brussels, and entrusted with editing the *Bulletin* of the Observatory. It was at this period of his career that the young *savant* invented his registering Telemétéorograph, which was made by Schubert, of Ghent, and was awarded a gold medal at the International Electrical Exhibition of Paris in 1881. Taking part in the Congress of Electricians in the same year, he was made Chevalier of the Legion of Honour. In 1880 M. Van Rysselberghe began the experiments in simultaneous telephony and telegraphy, with which his name is identified, on the wire running between the Brussels Observatory and the Meteorological Station at Ostend. In 1884, on giving the Belgian Government free use of his invention, M. Van Rysselberghe was appointed consulting engineer to the Telegraph Department of the Belgian Government, and was also made Chevalier of the Order of Leopold. Subsequently, in conjunction with M. Charles Mourlon, he was occupied in pushing his system of simultaneous telephony and telegraphy, and in devising an hydro-electric scheme for the town of Antwerp.

REVIEWS.

Electric Light Cables. By STUART A. RUSSELL. (London: Whittaker and Co., 1891.)

While an enormous number of popular and of elementary books have been written on electric lighting there are not half-a-dozen really first-class works on the market, if purely scientific treatises be excepted. Nothing has been written on dynamos which can be compared with the best books on the steam-engine; few authors have attempted to cover any one branch of the important subjects into which electrical engineering may be divided, and those who have succeeded best have confined themselves to special applications. The book before us may certainly rank with the half-dozen first-class books, and, so far from specialising, as might be imagined from its title, it covers the whole ground of the construction and use of conductors for the supply of electrical energy. A more thorough book could not have been written. With a minimum of theory, calculations when they are necessary are fully worked out, and with a maximum of practice the author has crammed every chapter with details.

One of the very few criticisms we have to make are upon the contents of some of the earliest pages. In discussing the Thomson law of maximum economy in conductors, and the various modifications which are necessary, he argues that, while the cost of a unit should include cost of fuel, &c., plus management and depreciation, the waste of energy in the conductors is a matter of fuel only; and since it is desired to get at the actual increase of expenditure on account of the energy wasted in conductors, so that it may be balanced against the annual charges for interest and depreciation on them, "it seems right in most cases to put on one side all the expenses connected with management, supervision, labour, and depreciation of buildings and fittings, and to include in the cost of unit only the extra expenditure on fuel, water, oil, petty stores, and the depreciation on the generating plant." We do not take exception to this argument, since it is saved by the proviso "in most cases"; but it is necessary to add that these cases include only those in which fuel is of importance, and in which the loss of energy is small. In cases where there is no fuel, as for example, where water is used, and where, at the same time, the loss in the conductors may be large, the position is very different. As soon, in fact, as the loss becomes appreciable, an appreciable part of the value of the buildings and plant must be allocated to it. The fallacy of writing 0 for the cost of fuel, but continuing to use the arguments which are fairly correct when coal is used, underlies nine-tenths of suggested schemes for using water-power or tidal-power. Mr. Russell makes, and probably would make, no such mistake, but careless readers might apply his arguments wrongly if not warned.

While containing more information than is to be found elsewhere on the manufacture and use of cables, no book that we have yet seen contains such valuable descriptions and comments upon the distribution, or, as the French say, "*canalisation*," of electrical energy. At the end of the second chapter in which the laws of economy, current density, and the size of conductors are discussed, a paragraph only is devoted to the considerations which demand that such theoretical conclusions must be modified by common sense. So much mathematical nonsense has been written about placing central stations at the centre of gravity of the system of lamps, and about the quantity of copper in imaginary networks, that the importance of these considerations might with great advantage have been amplified. The use of added resistance to short conductors, *versus* conductors of small section is sometimes necessary and is sometimes absurd. The author, with his extremely lucid working out of examples, might have given a case or two to elucidate this.

The effects of rise of temperature in wires under different conditions and fall of volts are fully discussed, and lead to a very good account of the various systems of distribution not only by different arrangements of conductors, but with reference to accumulators, transformers, and dynamotors. There is a little ambiguity about the effect of the magnetising current of Hedgehog transformers, which might lead the reader to imagine that they entail "the use of a conductor having 40 per cent. more area" than if continuous currents were employed. Mr. Mordey's table of virtual resistances is given, together with diagrams and fully worked out numerical examples of different systems of distribution. The author cannot help giving some conclusions which may, perhaps, be regarded as of less value than the details from which they are deduced. One of these is that "in a general way it is economical to use a high pressure alternating current with transformers whenever the average distance between the station and the lamps exceeds 1,000 or 1,200 yards.

Joint-making, various methods of insulating, leakage, and shocks are discussed, and the book contains very useful chapters on internal wiring, overhead wires, culvert and other underground systems, and concludes with methods of testing. The account of india-rubber cables is, as might be expected, very complete, but the author deals with rival insulators such as bitite, oil, Ferranti's system, and with air insulation in a very impartial and generous manner. It is, we regret, seldom that we can confidently and unreservedly recommend a book on electrical engineering; but we have no hesitation in saying that everyone engaged in electric light or heavy electrical work, if he has not already got it, should provide himself with a copy of this work.

Lessons in Heat and Light. By D. E. JONES, B.Sc. (London: Macmillan and Co.)

The best of all elementary physics laboratories is the world of every-day life. We are glad to find that Prof. Jones has introduced so many illustrations from that laboratory into his text-book, and that he has made so successful an attempt to elucidate the principles of physics by homely examples of their operation. It is, moreover, a pleasure to discover a work in which the evident object, an object which has been steadily kept in view throughout the treatise, is to *teach* and not to cram for examination. This book is divided into two parts. The first, on Heat, consists of fourteen well-illustrated chapters dealing with thermometry, calorimetry, thermal expansion of matter, and the modes of transmission of heat. Each chapter concludes with a number of numerical examples, the answers to which are given in an appendix. The second part consists of nine chapters on Light, each of which is concluded with numerical examples. The chapter on Photometry does not contain any reference to modern instruments for light measurement, nor is mention made of any other standard of light than the candle. There is no reason why elementary books should perpetuate old-fashioned instruments and methods, and ignore what has been done in recent years. In the chapter on the Velocity of Light we can find no mention of the medium in which the propagation takes place. The ether is ignored from the beginning to the end of the book, notwithstanding that in several places the wave-lengths of different rays are referred to. The phenomenon of aberration of light also is ignored; and nothing is said about the electro-magnetic theory. We are well aware that it is not quite orthodox to treat of these things in an elementary text-book; yet we are at a loss to understand why these conclusions of modern science are not to be described to the beginner as well as to the more advanced student. There is no necessity whatever to introduce complicated mathematics; it is quite possible to give a simple, intelligible account of the electro-magnetic theory without the use of a single equation or symbol. It is quite time that the text-books took a step forward and incorporated some of the researches of later years. The remaining chapters of the second part are devoted to the reflection and refraction of light, optical instruments, dispersion and colour; and are clearly and accurately written. We think every elementary student of physics should possess a copy of this work.

Electrical Experiments. By G. E. BONNEY. (London: Whittaker and Co.)

The author has been informed that "a large number of idle hours hang wearily on the hands of youths during the long winter evenings in country villages which could be spent in profitable amusement if they only knew how to use easily-

Hosted by Google

made electrical apparatus." He goes on to enumerate some eight of his own books, with prices. In these books the youths, who may form themselves into clubs for the purpose, are to find instructions for making the apparatus, and the present work tells them how to play with them. It is true that the author "hopes that the members of such clubs will not be content to merely find amusement. . . . but will go on from this to something higher."

Recreative science was all very well in the days of Guyot and Hutton, and may be said to have come to an end under Prof. Pepper. It may linger yet in the *conversazione*, and in the scientific toy; but whirling vacuum tubes, magnetic fish, electric pop-guns, and lead trees are very poor fun in themselves, apart from the science of which they are the fringe. It is doubtful whether any other subject has been thus trifled with. A banjo strummer need only develop his amusement and he may become a musician, the kodaker may become a photographic artist, the butterfly-catcher an entomologist.

With the exception of polarised light experiments in optics, which have real beauty, we cannot see any justification for wasting time in scientific pastimes. There is a wide gulf between this and Prof. Perry's top spinning and Prof. Boys' soap bubbles, even if it were only on account of the manual dexterity involved. The money value of a Gassiot's cascade, with the necessary accessories, would provide enough games of spillikins for 500 village clubs, and the recreative and technical value of the latter would be incomparably greater.

The Engineering Telegraph Code. By A. H. Blackburn and J. Stevens. (London.)

The object of this code may be illustrated by the following example which appears in the preface:—"Buy and ship as soon as possible portable steam crane, complete, with engines and boiler, mounted on wrought iron carriage. To lift 4 tons. Radius 16 feet. Gauge 4 feet 8½ inches. Send the same type as on page 10 in Jones' catalogue."—"*Lapade, Muehlseil, Larcenous, Prœluceam, Jones.*" Why telegraph companies should be bothered to send so cumbersome a word as "*prœluceam*" for "10" is best understood by the compilers. *Apropos* of "Jones' catalogue," the compilers seem to have approached one or two well-known firms, whose names appear very prominently in connection with apparatus which they do not pretend to manufacture. We do not, however, find any code words for "National Telephone Company's tram cars," or for "E.P.S. alternate current transformers," or for "The Elmore Wire Manufacturing Company's wire."

THEORY AND PRACTICE IN ELECTRICAL SCIENCE.*

BY ALEXANDER SIEMENS.

In his opening remarks the lecturer drew the attention of his hearers to the excellent exemplification of the advantage of the intimate association of science and practice afforded by the comparatively recent development with giant strides of electrical engineering as a branch of applied science. He laid great stress on the immense assistance which it had been to the practical electrical engineer to find so great a body of scientific material ready to his hand. The fact that the science of electricity had already been brought to an advanced stage of development had saved the practical electrical engineer from wasting years of valuable time and large sums of money in the fruitless experiments and groping in darkness which would otherwise have been inevitable. The engineers had shown how fully they recognised this indebtedness by naming the practical units which they employed in electrical measurement after the great discoverers who had developed the science of electricity. He pointed out, moreover, the manner in which the requirements of practical work had stimulated the further progress of purely scientific investigation. He specially mentioned, as an illustration of the assistance which electrical engineers had derived from scientific investigation, the discovery, communicated by Dr. John Hopkinson to the Institution of Civil Engineers, that alternators could be run in parallel. Dr. Hopkinson had been led to this result by mathematical theory. Dr. Hopkinson had subsequently discovered that he had been anticipated in this by Mr. Wilde, and had communicated this fact to the Institution.

The lecturer then passed on to the consideration of the numerous practical applications of electricity to the requirements of every-day life. Referring to the question of heating by electricity, he did not believe it could be commercially successful in such a place as London, for example, where the electrical energy corresponding to the energy in a farthing's worth of coal cost about 1s. 10d., but it was quite another question where water-power was abundant. This was the case in Norway, and in that country electrical heating was now extensively used in nail making. The process of making a coiled spring out of a thick steel rod by means of an electrical furnace was then exhibited, showing how perfectly the temperature was under control. This was a point of great importance in this particular case, as it enabled the workman to produce a spring of extremely even temper throughout. The current used in this experiment was obtained from the Deptford supply mains at a pressure of 2,400 volts, transformed down to 15 volts.

The lecturer considered it absurd to ascribe the origin of the electrical transmission of power to an accidental discovery of the reversibility of the Gramme dynamo at the Vienna Exhibition of 1873, and pointed out that Jacobi had employed an electric launch as early as 1839. He informed his audience that Sir William Siemens had told him that his brother Werner Siemens had inferred the reversibility of the dynamo from the known reversibility of the magneto machine. As an illustration of the advantages of employing electromotors for driving machinery even in large factories he pointed out that at his own works at Woolwich the employment of electromotors had enabled them to concentrate the 1,200 H.P. engines required in the factory within a ground space only 32ft. by 25ft. They found that a great saving was effected by replacing the numerous small engines previously employed by a small number of large engines. The reason of this was chiefly owing to the well known fact that it is possible to make large steam engines much more efficient than small ones, and to the reduction in the wages bill owing to the smaller number of engine drivers required. The electrical distribution of power was also much more economical when only part of the machinery was in use than the older method of employing belts and shafting. Another great advantage was the facility of altering the speed of any one machine independently of that of the others. This cheapening of power was a matter of great importance, as cheapening power meant cheapening production. Moreover, when a supply of electrical power from a central station was available it was of special advantage to the owners of small factories, both on account of the diminution of capital expenditure and on account of its enabling them to dispense with the small, and consequently comparatively inefficient, engines which would otherwise be required.

Referring to the Lauffen electrical transmission of power at high pressure, the lecturer considered the result, an efficiency of 75 per cent. over a distance of 110 miles, extremely satisfactory from a scientific point of view. The practical difficulty, and consequent expense, however, of effectively insulating conductors carrying currents at such a high pressure, prevented this method of transmission from being of practical use.

A number of very brilliant experiments, illustrating the difficulty of insulating conductors for very high pressure, were then shown. These included the passage of the current under a pressure of from 30,000 to 50,000 volts through a log of wood and slabs of marble and slate, also the breaking of a large sheet of glass. These experiments were considerably more brilliant than those which had been shown at the Crystal Palace, owing to the much higher capacity of the mains. This large capacity was partly due to the current being taken from the Deptford mains, and was further increased by passing the current through about 300 yards of twin cable, which was employed with the object of obtaining as high a capacity as possible.

* Abstract of Friday evening Discourse delivered at the Royal Institution, February 3rd.

Hosted by Google

THE LIVERPOOL OVERHEAD RAILWAY.

On Saturday last the Marquis of Salisbury formally opened the Overhead Railway in Liverpool, which has been in process of construction for the last three years; the line is carried overhead upon a structure built up almost entirely of steel, at an average height of 16ft. clear above the ground, with the exception of about 270 yards, where it runs over an embankment and passes underneath an existing line belonging to the Lancashire and Yorkshire Railway. Many novel features have been introduced into the design of the structure and the method of erection employed; in the length of the line there are three tilt and a swing bridge, which are opened to allow of traffic passing underneath, the swing bridge being over the entrance to the Stanley Dock. The construction of the line and its equipment have been carried out under the direction of Sir Douglas Fox and Mr. J. H. Greathead, the engineers to the Overhead Railway Company. After careful consideration electricity was adopted as the means to be used for working the trains, signals, and lighting the stations. The contract for the whole of the plant was placed in the hands of the Electric Construction Corporation (Limited), Wolverhampton, and has been carried out by them under the personal superintendence of Mr. Thomas Parker, their chief engineer.

The railway is six miles in length, with a double line of rails 4ft. 8½in. gauge; the gradients throughout are easy, only in one case there being a dip of 1 in 40. The quickest curve has a radius of six chains. Fourteen stations give the necessary facilities for taking up and setting down passengers, the maximum distance between any two stations is 1,200 yards, and the minimum 300 yards, the latter being in the City at the centre of the line. It is intended that the line shall eventually be extended for a distance of one and a half miles at each end, thus bringing up the total length when completed to nine miles. The six mile journey from one end of the line to the other will be completed in thirty minutes, this including a stop at each station. The generating plant is at the Bramley Moore Dock, adjoining the railway and about the centre of its length. The station building (*see* Fig. 1) has been formed by building up some of the arches under an existing overhead railway belonging to the Lancashire and Yorkshire Railway Company, and used for bringing coal to vessels in the dock. Steam is generated by six Lancashire boilers, 8ft. diameter, 30ft. in length, the outer shell being $\frac{21}{32}$in. thick, and the flues $\frac{1}{2}$in. thick plates; the working pressure is 120lb. per square inch. The boilers are

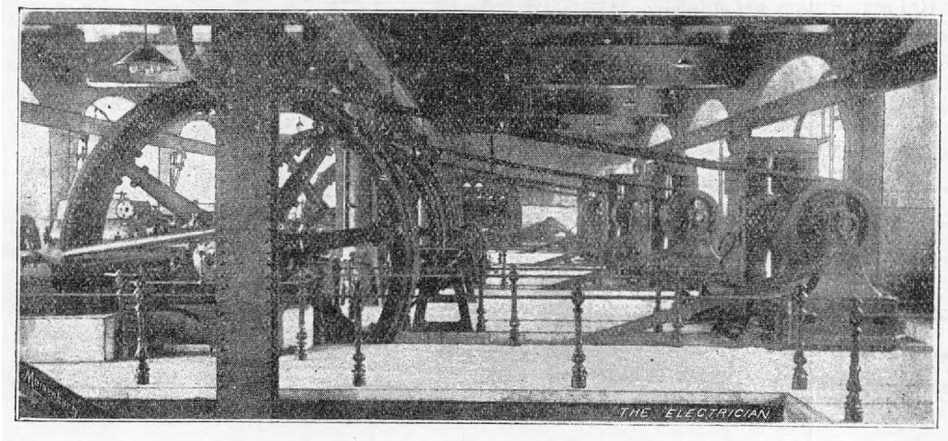

FIG. 1.—Generating Station of the Liverpool Overhead Railway.

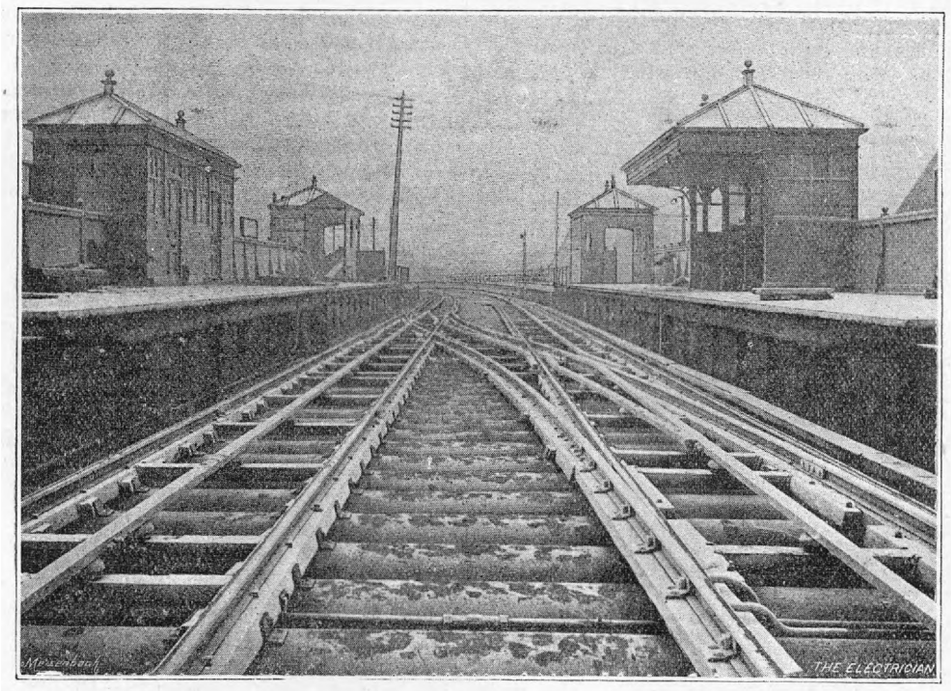

FIG. 2.—Single Cross-over Road at Intermediate Station

Hosted by Google

fired by Vicars' mechanical stokers, these being supplied with coal by a conveyor from the large hoppers fixed in the roof of the boiler house and into which the trucks bringing the coal on the overhead line are directly discharged. An economiser in the main flue utilises the waste heat for raising the temperature of the feed water.

There are four main engines of the horizontal coupled compound type, each capable of indicating 400 H.P., with 120lb. steam pressure, at 100 revolutions per minute. The cylinders are 15½in. and 31in. diameter, 36in. stroke, both fitted with Corliss' valve gear. The heavy flywheels, 14ft. diameter, are each grooved for 19 1¼in. diameter ropes. A barring engine, with countershaft and gearing, is provided for turning round or starting the engines. The exhaust steam is taken to a separate surface condensing plant, which has been erected in duplicate, each set being capable of dealing with the steam from three of the main engines when working up to full load. The circulating water is obtained from the dock adjoining. Auxiliary engines are provided for driving the air and circulating (centrifugal) pumps of the condensers, boiler feed pumps, stokers, conveyor, and economiser scrapers. All the steam and feed pipes are arranged to give a duplicate service between the boilers, engines, and pumps.

Each of the main engines drives by means of cotton ropes an Elwell-Parker shunt-wound two-pole dynamo, giving an output of 500 volts, 475 amperes, at 400 revolutions per minute; the magnets are of the double horse-shoe type fixed vertically, and divided on the horizontal centre line, so that the top half can be readily taken off to allow of the examination or removal of the armature. The pulley is carried between two bearings, and a coupling being inserted between the pulley and armature shafts allows the latter to be taken out without dismounting the pulley, taking off the ropes, or interfering with the set of the bearings. The switchboard is of a very simple description, as all the dynamos couple in parallel on to omnibus bars, from which the current passes out to the line; each machine is provided with a multiple contact-switch and set of resistance coils for regulating the E.M.F., a voltmeter, an ammeter, and a double-pole Elwell-Parker patent automatic magnetic cut-out, which also acts as the switch. Between the omnibus bars and the line is a main automatic magnetic cut-out carrying the whole current going out from the station.

The current is carried along the line for supplying the motors by means of a steel conductor laid in between both up and down lines. This conductor, which is made of a special quality of steel, having a high conductivity, takes the form of a channel, having a sectional area of 4 square inches and weighing 40lb. per yard; the various lengths are jointed by copper fish plates arranged to allow for expansion and contraction. The conductor is carried upon pot insulators, a thin sheet lead cap being inserted between the channel and the insulator. As the ordinary rails are carried by longitudinal sleepers, special cross bearers have been fixed to carry the insulators. At each of the intermediate stations there is a cross-over road, and at each terminal station two cross-over roads; these are features which introduce difficulties in working to prevent short circuiting between the conductor and the ordinary rails which form the return circuit. Mr. Parker has overcome this by fixing the height of the centre conductor so that its surface is about 1in. higher than the top of the ordinary rails (Fig. 4), and the collectors being made very wide it bridges across from the conductor on one side to that on the other side of the ordinary rail. The arrangement can be better understood from the illustrations (Figs. 3 and 4) than by a description. The conductors on the up and down lines are electrically connected at each cross-over road, as are also the ordinary rails, thus making a network of conductors. The ordinary rails are electrically jointed across the fish plates.

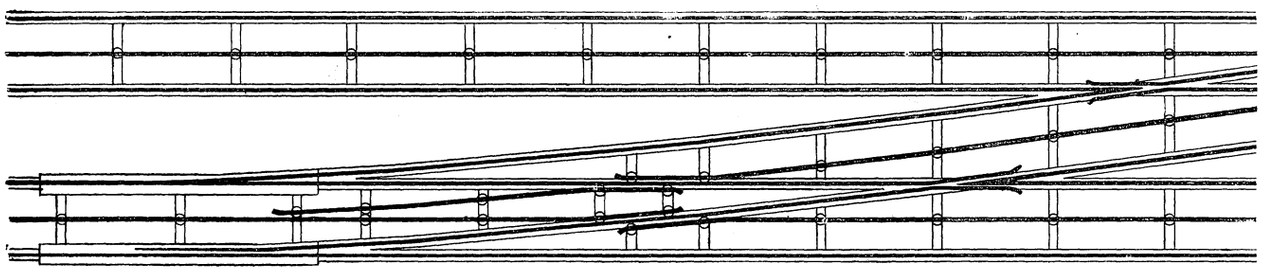

FIG. 3.—Plan of Points and Cross-over Road.

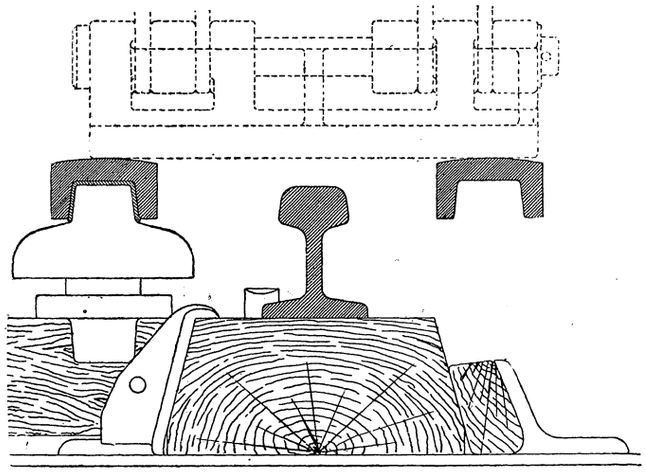

FIG. 4.—Section of Conductor Crossing.

The collectors (Fig. 5) consist of hinged cast-iron blocks carried by, but insulated from the bogie frame; one is fixed to each carriage. The carriages, 45ft. in length over the end pillars and 8ft. 6in. in width over the side pillars, are carried by two four-wheel bogies, having 32ft. centres and 7ft. wheel base, the wheels being 2ft. 9in. diameter. Each carriage has a seating capacity for 57 passengers—16 first and 41 second class. Two carriages form a train, which weighs approximately when complete with motors, switches, and full complement of passengers 40 tons. A driver's box is partitioned off at one end of each carriage, and fitted with the driving switches and brake gear; the box at the front of the train is occupied by the driver, and that at the rear by the guard, who is also trained to take charge of the driving in case of emergency, a gangway between the two cars giving a means of communication. Westinghouse brakes, which are fitted in addition to hand brakes, derive their supply of compressed air from receivers

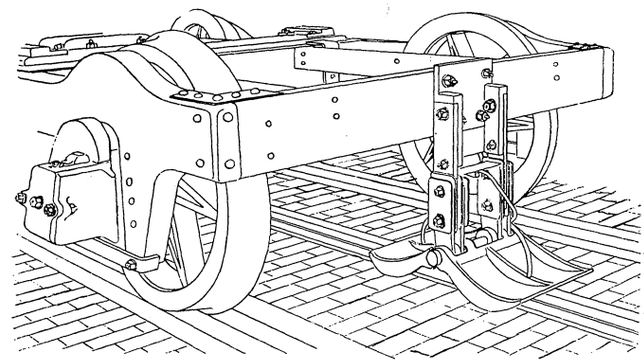

FIG. 5.—Slipper Collector fixed to Bogie Frame.

Hosted by Google

carried under each carriage, these being charged at the north terminal station, where an air-compressing plant is erected. One bogie of each carriage carries a motor, the trains being made up so that there is a motor on the leading bogie of the first carriage and one on the trailing bogie of the second carriage. The motor armatures are mounted directly upon the axles, 10 revolutions of which are equivalent to a train speed of one mile per hour, and as a speed of 25 to 30 miles per hour is required to complete the journey in 30 minutes, this gives a speed to the motor armature of 250 to 300 revolutions per minute. The magnets are supported by two bearings on the axle, and, in addition, by a special arrangement of springs from the bogie frame.

The motor magnets are of the double horse-shoe type series-wound, the armature being of the "drum" type. The dimensions and winding were determined upon after careful experiments carried out by Mr. Parker, the object being to arrive at the most economical arrangement, having in view the fact that the greater part of the work which the motors are called upon to perform is that of starting and accelerating the trains; only for a very few minutes during each journey are they run up to full speed. Some tests taken at the Electric Construction Corporation's works showed that when the motor was stationary and a current of 30 amperes passed through it the torque effort on the rim of the wheel (2ft. 9in. diameter) was 170lb., with 50 amperes 450lb., and with 80 amperes 1,060lb.

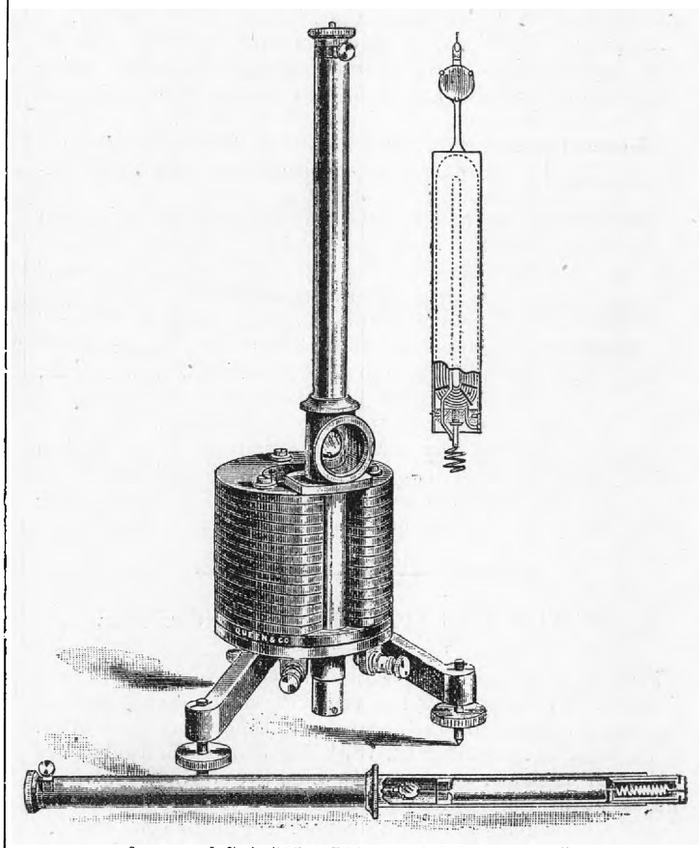
The carriages are lit with glow lamps supplied with current from the centre conductor. At each of the 14 stations along the line is an accumulator of 54 cells, forming two batteries each of 27 cells. One battery at each station to the south of the generating station are connected in series and charged off the 500-volt circuit, a second loop taking in the batteries at stations to the north of the generating station. These batteries furnish current for lighting the stations, and also for working the automatic signals. Home and starting signals are fixed on up and down line at each station, and connected up with the necessary making and breaking contacts, the latter being worked by a striking bar on the train when it passes over. Each train as it goes along automatically blocks the one section in the rear. Glow lamps in duplicate are used in the signal lanterns at night.

To carry out the work several firms have been engaged as sub-contractors — the boilers, engines, and other portions of the steam plant having been supplied by John Musgrave and Sons (Limited), Bolton; the carriages by Brown, Marshalls, and Co. (Limited), Birmingham; the steel channel by the Shelton Iron and Steel Company (Limited), Stoke-on-Trent; the signals by I. A. Timmis, London, &c. The whole of the electrical plant has been designed and manufactured at the Electric Construction Corporation's works at Wolverhampton, they also being responsible for all other portions of the plant.

ANOTHER "NEW" GALVANOMETER.

Closely following on the heels of the "New Standard Ballistic Galvanometer," described in our issue of December 16, 1892 (p. 187), an account of another "chestnut," the "New Queen d'Arsonval Galvanometer" appears in the Journal of the Franklin Institute. We are not prepared to accept the doings of a single firm as representative of a whole nation, or we should have to confess that at last some subject had been found in which Americans had no originality. This appropriation of the design of one of our latest English instruments is not quite so cool as the case of the ballistic galvanometer, since the Paper on "Recent Improvements in d'Arsonval Galvanometers," by Mr. N. H. Genung, not only acknowledges the existence of the Ayrton-Mather instrument and refers to our description of it (*The Electrician*, Vol. XXIX., p. 336), but quotes from the joint Paper of these authors with Dr. Sumpner (*The Electrician*, Vol. XXIV., p. 348), and Mr. Mather's Paper on "Shapes of Moveable Coils used in Electrical Measuring Instruments" (*The Electrician*, Vol. XXIV., p. 577).

When we learn, moreover, that an Ayrton-Mather galvanometer was exhibited at the reading of this Paper, we need only regard the "New Queen d'Arsonval Galvanometer" as an American edition of this instrument, and examine the modifications which have been thought necessary to adapt it for the American market. The puny height of 6in. was unworthy of the occasion, so another 10in. or more have been clapped on to it. The miserable little coil designed by Mr. Mather has, like the toad in the fable, swollen hugely, and has attained a bulk about eight times that of the original; while the magnet



Queen and Co.'s "New D'Arsonval Galvanometer."

is about four times as great. Most of the other changes have been in the direction of greater elaboration, one exception being the absence of a spirit level; it will be remembered that in their copy of the Nalder galvanometer the Queen Co. omitted the level as a needless refinement. If the detail drawings of the instrument given in the Journal of the Franklin Institute are to scale, it seems that the clearance between the coil-tube and the case-tube is so small that very careful levelling will be necessary to allow the coil to swing freely. The most sensible way of levelling is to use a level; of course, there are other ways, one of them being to fidget about with the screws until the coil swings. If this operation really suits American electricians, we may distinguish it as "leveling." The most noticeable alteration is the construction of the magnets from stampings of sheet steel and the rounding off of the corners, to concentrate the field and to avoid waste. This is very proper, but we learn that these magnets are "hardened glass-hard," and "after having been thoroughly magnetised, great care is exercised not to subject them to any rough usage." No amount of allowance for peculiarities of transatlantic requirements can convince us that such magnets would not be all the better for a little knocking about, with the deliberate intention of "ageing" them.

Coil Tube and Mirror of Ayrton-Mather-D'Arsonal Galvanometer.

The increase of size and possibly the additional strength of field has produced a distinct advance in the absolute sensitiveness, by which we mean the deflection produced by a given current, irrespective of the time of oscillation, for one volt

Hosted by Google

gives one millimetre deflection at a metre scale-distance through 200 megohms. This sensitiveness, however, is gained at the expense of quickness, for an interval of about 55 seconds is required to deflect the coil to its steady position, the movement being aperiodic. As regards proportionality of deflection to current, this instrument leaves much to be desired, the discrepancy amounting to between 4 and 5 per cent. English instruments, from one of which this has been copied, have an error of less than one-tenth per cent. in this proportionality.

Accurate proportionality of deflection to current depends upon very delicate adjustment and shaping of the magnet poles relatively to the shape of the coil. If these are blindly imitated in Chinese fashion, fair proportionality may result, but if either poles or coil are altered, some intelligent knowledge and experience of the instrument or a considerable amount of tentative experiment would be needed to secure it.

The slipping out of the tube, the shape of the coil, and the flattened phosphor-bronze suspension are all too simple to bear any improvement. "To the top of the aluminium tube," says the Paper, "is attached the mirror, held in place by a three-armed aluminium clip, thus avoiding the use of wax." The three-armed clip referred to is clearly shown in the illustration which was published in *The Electrician*, Vol. XXIX., p. 336, and which was engraved from a drawing made from an instrument lent to us for the purpose by Mr. Paul. We shall watch with interest the Americanization of other English instruments, and trust that those which have the honour to be thus translated may be worthy of the selection by the appreciative instrument makers of Chestnut-street, Philadelphia.

THE ELECTRIC LIGHTING OF SINGAPORE.

For some time past the question of electric lighting has been discussed in Singapore, and a very interesting correspondence has been published in the local papers concerning the matter. So far back as November 18, 1891, Mr. James MacRitchie, the municipal engineer, wrote to Mr. Lindsay, of Glasgow, who is the agent in Europe for this Municipality, stating that the Municipal Commissioners of Singapore had under consideration a proposal to light the town, or a portion of it, with the electric light. Before, however, deciding upon any particular course they were anxious to obtain for their guidance particulars as to the systems adopted in other towns where electric lighting was used, as well as the success obtained, cost of installation, prices charged to customers, &c. With this letter was enclosed a schedule containing inquiries, which were to be forwarded to various towns and electric supply companies, with the view of obtaining answers which would assist the Commissioners in Singapore in settling the question. These circulars were sent out, and the replies were returned to Mr. MacRitchie, who furnished a report to the Municipal Commissioners, dated April 7, 1892. In this report he points out that before the list of questions was issued it was submitted to Prof. Jamieson in Glasgow, who made slight alterations, and out of the large number of circulars issued, only 11 replies were received, these being from Liverpool, Waterford, Norwich, Bradford, Dublin, Taunton, Exeter, Bristol, Chelmsford, Westminster, Notting Hill, St. James and Pall Mall. Of those sent to America not a single schedule was filled in. Besides the above data, the municipal engineer collected details of cost from periodicals, and obtained them direct from Hong Kong and Shanghai; he also obtained additional information from a firm in Calcutta.

It will be well before proceeding to give an abstract of this report to consider the amount of lighting which is required in Singapore. It appears that at present there are 883 gas lamps used for the public lighting, each lamp giving about 15 c.p., and the gas company of course supplies a considerable quantity of gas to private consumers. The Municipality pays at the rate of 6s. 5d. per lamp per month, while the charge to private customers is 9s., less 10 per cent., per thousand cubic feet. It may be well to remark that the amounts quoted in the report of the municipal engineer and also in the correspondence are given in dollars, and it appears that the rate of exchange is taken at 6·7 dollars to the pound by the municipal engineer, and at 6 dollars to the pound by Mr. Thomas, whose name will appear later. We have, however, transformed all the amounts into English money. The public lamps burn five cubic feet of gas per hour, and are lighted eleven hours per night, so that they use 1,650 cubic feet per month, which at the rate charged to the ordinary consumer would amount to 13s. 4d. per month, or rather more than double the amount charged for public lighting. The position of Singapore near the Equator renders the question of public lighting simpler than it is in other countries. The light is required regularly eleven hours per night, and this, of course, is a distinct advantage in favour of electric lighting, and would lead to a better load-factor than can be obtained in Great Britain. This fact has been brought very prominently forward by several gentlemen who took very different views of the matter from those put forward by the municipal engineer. Major MacCallum, of the Royal Engineers, who holds the position of colonial engineer, has shown great interest in the question, and is a strong advocate for electric lighting; feeling, however, that he is not an expert upon the question, he has availed himself of the assistance of Mr. Thomas, who is strongly in favour of using alternating currents and arc lamps.

Major MacCallum proposed to replace the 883 public lamps as follows:—To use 250 arc lamps of 1,200 c.p. each instead of 600 gas lamps, and to replace the remaining lamps by 283 oil lamps at 6s. per month each. The reason for proposing oil lamps was that these lights were very much scattered, and the arc lamps were to be used in the more densely populated part of the town. The proposal was that overhead wires should be used, and it was thought that these would not be objectionable, as there are at present a great number of overhead telephone wires. Major MacCallum's proposal did not contain any allowance for private lighting, and from the figures given to him by Mr. Thomas he considered that the total cost would work out to £25,000, and the annual cost per arc lamp was put down at £13. 13s. The municipal engineer states in his report that he has carefully gone into the proposals made by Major MacCallum and Mr. Thomas, and the main objection in his mind appears to be that if the gas company were not allowed to supply gas for the public lighting they would not be able to carry on their own business at a profit. It is hardly an argument against the introduction of public electric lighting that if it were undertaken the gas company would suffer. It must be distinctly borne in mind that in such a place as Singapore the hours of lighting are practically constant throughout the whole year, and as we have remarked previously amount to about 11 hours per night. In the case of an arc-light installation, therefore, the conditions of supply would be eminently favourable from a financial standpoint, and the figures which have been obtained by Mr. MacRitchie from central stations in Great Britain are of little use in such a case.

In his report the municipal engineer has made free use of the details which have appeared from time to time in the columns of *The Electrician*, and both he and Mr. Thomas acknowledge the great assistance which has been afforded to them by our yearly reports on the condition of the various supply companies, and from the tables published in "The Electrician" Electrical Trades' Directory and Handbook. Mr. MacRitchie, in his report, does not consider Major MacCallum's proposal as originally framed, but has taken it to be a scheme for arc-lighting in the public streets, and also for private supply as well. This gives an entirely different aspect to the question, and we think it is hardly a fair treatment for the proposal. From this voluminous report we have been able to gather little which cannot be obtained from our own columns. Mr. Thomas had supplied data of arc-lighting upon the Thomson-Houston system, of which he has had much experience, having been in charge of the Taunton Station for some time. He claims that the arc lights can be supplied in Singapore for the sum of £13. 13s. per annum, or at the rate of 22s. 9d. per light per month, and that in this way the town would obtain 30 times as much light as it is now getting from the gas lamps. Mr. MacRitchie gives details of the charges made by the electric lighting companies to the municipal bodies in Eastbourne, Taunton, Dublin, and various other towns, and upon

Hosted by Google

these charges bases his estimate for the cost of arc lights in Singapore. His argument is that in the first place plant erected in Singapore would cost 25 per cent. more than similar plant erected in England, and that whereas the cost of coal at such a place as Taunton was only 13s. per ton, the price of coal in Singapore is £1. 10s. per ton. Mr. MacRitchie quotes the cost per arc lamp at Taunton at £22 per annum, and remarks that this is only for eight hours per night; he therefore concludes that the price at Singapore per light would be considerably more, and considers that Major MacCallum's estimate is too low. The whole of the municipal engineer's arguments appear to be based on a fallacy. He has considered the charges made by electric lighting companies to public bodies as though these were the actual costs of production. This, of course, is obviously absurd, and Mr. Thomas has very rightly drawn the attention of the public to the fact that the cost of running arc lamps in St. Pancras district is only £12 per annum. The gas lamps, as quoted by Mr. MacRitchie, are 75 yards apart, and there are 930 lighting some 40 miles of street; this number does not agree with the figures which we have given above, and which were supplied previousiy to Major MacCallum. It appears to us that 250 arc lamps of 1,200 c.p. each would give a very satisfactory improvement upon the lighting obtained from 600 gas lamps. We think Mr. Thomas's is a figure for which the work might be done considering the special conditions of such a town as Singapore, and in order to give the authorities an opportunity for seeing arc lamps in use, Mr. Thomas has proposed to run 18 Thomson-Houston arc lamps of 1,200 c.p. each for a month. These lamps would be placed on wooden poles at 100 to 150 yards apart in the public roads, and would be supplied with current from a Thomson-Houston machine, driven by an 8 H.P. portable steam engine. He is willing to run this installation for one calendar month for the sum of £158. In the event of the Municipality providing the necessary engine, boiler, and shed, a reduction would be made of £54. We can only say we trust that before long Singapore will be sufficiently enterprising to take up the question of electric lighting, although the rate of interest—6 per cent.—which the Municipality has to pay upon loans is somewhat excessive according to home ideas.

According to latest advices the Municipal Commissioners have refused Mr. Thomas' offer by five votes to four, the President stating that he expected every day to get an offer from the Gas Company with regard to the street lighting.

THE DEVELOPMENT AND TRANSMISSION OF POWER FROM CENTRAL STATIONS.*

BY PROF. W. CAWTHORNE UNWIN, F.R.S.

Systems of Hydraulic Transmission. Accumulator v. *Reservoir Storage.*

The lecturer said the introduction of the system of distributing energy by water pressure was due to Lord Armstrong. The high-pressure system of hydraulic transmission was almost exclusively an English system, and almost exclusively a system for working intermittent machines. For ordinary power purposes it was not so well adapted, and it was abroad, and at a later date, that hydraulic transmission had been carried out and adopted for the supply of power for all ordinary industrial purposes. The intermittent action of cranes and other similar machines led to the study of means of storing energy. Reservoir storage was not at first possible, and it occurred to Lord Armstrong that air pressure might be used. But there were practical difficulties. Air pressure varied with the variation of the quantity of water in store in the air-vessel; an air-pump must be used to replace the air absorbed by the water and to maintain the air-cushions in the air-reservoir. Subsequently, Lord Armstrong invented the accumulator, which answered the purpose of meeting momentary fluctuations of demand in hydraulic systems driving intermittent machinery. As early as 1840 Lord Armstrong had completely worked out the idea of a system of power distribution. The systems of hydraulic transmission might be divided into two groups. First, there were the systems with reservoir storage, which for convenience he would call low-pressure systems. In none of these cases did the pressure reach anything like the amount it did in the Armstrong system, but they were of very high pressure all the same, and he only called them low pressure for the sake of distinction. In these systems the pressure was fixed by local conditions, and usually was not equivalent to more than 400 to 600 feet head (170-260lb. per square inch. By low pressure systems they had power distributed for all ordinary industrial purposes, for continuous as well as for intermittent machines. In the second group were systems with accumulator storage, worked usually at very high pressure, 700 to 800lb. per square inch, or 1,600 to 1,800 feet of head. In these systems the energy was distributed almost exclusively for lifting purposes and for driving presses, or for other similar intermittent machinery.

* Howard Lecture IV., delivered before the Society, of Arts Friday, February 3rd.

Advantages and Limitations of Hydraulic Transmission.

He proposed first to glance at some of the mechanical advantages of hydraulic transmission. First, just consider the amount of power which could be transmitted in pipes by pressure water. The velocity in the pipes could not be made great without excessive frictional losses and without incurring danger from hydraulic shock. A velocity of 3ft. per second was commonly allowed, and perhaps this might be doubled without excessive frictional loss or excessive risk. With a speed of 3ft. per second, and a low pressure of 500ft. head (215lb. per square inch), such as that of Zürich, a 12in. main would transmit 133 H.P.; with a 24in. main about 533 H.P.; with a very high pressure of 750lb. per square inch, like that in London, or a 6in. main transmitted 116 H.P., and a 12in. main, if it could be used, which was not certain, would transit 463 H.P. The horse-power was gross horse-power, without any allowance for waste at the motors. It would be seen that neither on the high nor the low pressure system was the amount of power which could be transmitted by a single main a very large quantity. This at once marked out a characteristic limitation for hydraulic transmission. It was therefore best adapted for intermittent machines. If applied continously, it was best adapted to motors of comparatively small size used in industries not requiring great amounts of power. When they came to deal with thousands of horse-power, the hydraulic transmission system broke down from the excessive size of the mains to be used. That was the first point. The second point was the loss of pressure in the mains due to friction. At 3ft. per second the loss of pressure per mile was very small in amount, about 18lb. per square inch in a 6in. main, only 9lb. per square inch with a 12in. main, and 4½lb. with a 24in. main. These losses were quite insignificant on the high-pressure system, and not very important on the low-pressure system with ordinary distances of transmission—that was, distances of a mile or more; in fact, the question of loss in the mains might be put aside as perfectly insignificant in the cases to which hydraulic transmission was properly applicable. A third point was the considerations arising out of the strength of the pipes. In all hydraulic systems at high pressure in this country cast-iron pipes had been used, with a peculiar flanged joint introduced by Lord Armstrong. The jointing material was gutta-percha, but the form of the flanges had been modified by Mr. Ellington. Pipes subject to high pressures were usually jointed as shown in diagram (Fig. 1). [In Fig. 2. the new type of joint is shown.—Ed. *E.*] The working stress on these cast-iron pipes was 2,800lb. per square inch of metal, a very moderate limit of stress. Probably at this time welded steel pipes could be used for hydraulic transmission at high pressure, if a suitable joint for them could be devised. Such pipes were proposed to be used in the project submitted to the Niagara Commission by MM. Vigreux and Levy, but he (the lecturer) did not know of any system where they had been actually used. A stress of 15,000lb. per square inch might be used with such pipes, and this would, no doubt, greatly increase the applicability of high-pressure transmission. On low-pressure systems cast-iron socket pipes had.

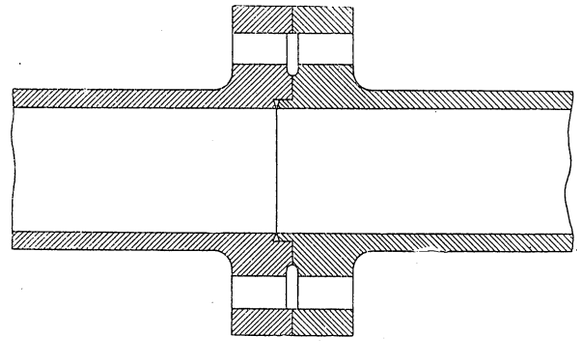


Fig. 1.—London Hydraulic Power Company's Joint (Old Pattern).

Hosted by Google

been alone used, so far as he knew; but on such systems steel pipes might be advantageously used in many cases. Examination showed that, as far as strength was concerned on low-pressure systems cast-iron could be used in all cases, but for high-pressure systems it was doubtful whether cast iron could be used in mains more than 6in. in diameter. There came in a practical limitation to the amount of power which could be transmitted on high-pressure hydraulic systems. Then there came a further consideration arising out of the weight and cost of the pipes. For pipes of equal strength it appeared that the weight was simply proportional to the horse-power transmitted; hence, so far as cost of mains was concerned, the low-pressure system was as economical as the high-pressure system. That, of course, did not allow for such practical exigencies as perfect pipes being made of the thickness determined by conditions merely of strength. No doubt, the practical exigencies taken into account, a given amount of power might be somewhat more cheaply distributed in high pressure than in low-pressure systems. That, perhaps, cut across a popular impression, but he believed it was the case that if they could make their pipes always to suit the exact conditions required for strength, the low pressure would be as economical in distribution in most cases as high pressure.

Next came considerations arising from motors driven by the pressure water. On all very high-pressure systems the motors used were almost exclusively pressure engines. Such motors became extravagantly expensive, if driven by low pressure water; the greater the water pressure the more conveniently and cheaply the power was produced in machinery of that kind, and hence it had

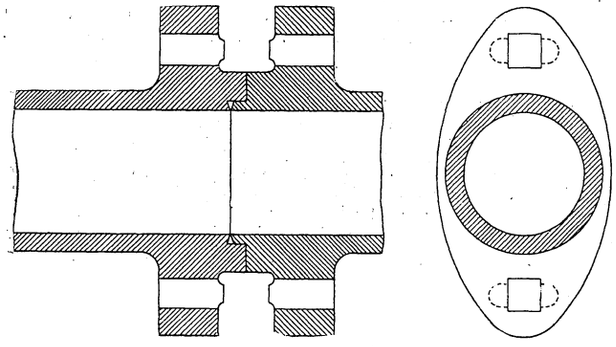

FIG. 2.—London Hydraulic Power Company's Joint (New Pattern).

come about that all the English systems of water-pressure distribution, which had been intended for working pressure engines, had been constructed for pressures of 700lb. to 800lb. per square inch. These systems were extremely convenient for actuating lifting machinery, for presses, and even for rotative motors of small power, but were not nearly so convenient when a considerable amount of power was required continuously for driving a factory. For that purpose turbines were more convenient, and for turbines the high-pressure English system of distribution was not convenient; the reservoir system in that case was very much better adapted.

Hydraulic Power Stations (Accumulator System), Hull, London, Birmingham, Manchester.

The earliest general system of high-pressure hydraulic transmission was one installed in the town of Hull. He believed that was the first system in which power was sent from one station to many consumers. It might be said that that was a purely local system, covering no great area of town, the longest main being but 1,500ft. in length. The efficiency of the whole system was said to be 76 per cent. The tariff adopted in Hull for working cranes was £52 for one crane in one warehouse, with a diminishing price for many cranes in one warehouse. The Hull charges were equivalent to from £104 to £83 per horse-power per annum.

Now he came to the London Hydraulic Power Company's system. An Act was obtained in 1871 for supplying hydraulic power in London on the Armstrong system. The power conferred by the Act remained dormant until resuscitated by Mr. Ellington in 1882. The present company was constituted in 1884. In 1887 twenty-five miles of pressure main had been laid in London streets, and at the present time there were 59 or 60 miles of pressure mains under the London streets. There were three principal pumping stations, one at Falcon Wharf, another at Millbank, and another at Wapping, whilst a fourth station is soon to be erected. The whole of the water was taken at the original station from the river, but it was filtered before it was used. The filtered water was pumped into the high pressure mains, then used by the consumers, and from the consumers flowed away into the sewers. The power was available night and day all the year round, and was largely used for lifting machinery. The charges were based on the power taken by both large and small consumers. The company claimed that it could be used for electric lighting of particular establishments, and it certainly could be used for extinguishing fires by the application of an ejector. The quantity of water used by each consumer was measured by a meter on the discharge main. Now, the London system was an exceedingly remarkable one, which had grown up comparatively rapidly but very silently until it had become a large institution.

He wanted them now to look at the charges for water-power on the London hydraulic system. A minimum charge of £5 per annum was made for quantities not exceeding 12,000 gallons per annum; the charges varied according to a sliding scale, and for 15,000 gallons the charge amounted to £8 per annum, or about 8s. per 1,000 gallons. For a consumption of a million and a quarter gallons the charge was £170, or little more than 3s. per 1,000 gallons, so the variation in the charge for water was considerable. With these charges the cost of power for the kind of work for which the system was best suited were often very small. It had been calculated that very often the charge for the water used for lift machinery amounted to less than ¼d. per ton lifted 50ft. On the other hand, in these lectures it was necessary to compare the cost of power on some common basis, and it was unavoidable to take as a basis the work of ordinary machines going continuously throughout the day. If they took the power supplied by the London Hydraulic Company, supposing it to be used for machines working 3,000 hours per year, then the cost would be very considerable. Allowing an efficiency of 80 per cent. in the motor, they would find they had to pay the Company £175 per horse-power per annum if they took a motor of the smallest size for which they supplied power, or £62 per horse-power per annum if they had a motor of the largest size. In either case the charge for continuously exerted power turned out to be a very large one.

Since the establishment of the London hydraulic system the same system had been extended to some other towns, and in connection with them he would just point out, first of all, that in some of them attempts had been made to use water from the town mains for power purposes. In Liverpool, for instance, pressure water on the street mains was used as early as 1847. From an interesting Paper by Mr. J. Parry, it seemed that the use of hydraulic pressure from the town mains made very slow progress for thirty years. In 1887 the number of machines supplied was 89, and at the present time 162 machines in Liverpool were worked by pressure from the mains, consuming about 125 million gallons of water per annum. In the Liverpool mains they had a very good pressure, about 70lb. per square inch, and he found that the whole of the power taken from the water mains in Liverpool amounted only to 82,000 H.P. hours in the year. Therefore the whole of the power taken from the town mains in Liverpool only amounted to 27 H.P. taken continuously from the mains during 3,000 hours in one year—a very small power, indeed.

In Birmingham lately they had been extending a system strictly on the lines of the London system—the high-pressure system. He referred to the Birmingham system mainly because, in the first place, it was a municipal system. In the next place, in Birmingham they were making an experiment by working their central pumping station with gas-engines. There were three triple hydraulic pumps, pumping at a pressure of 730lb. per square inch in the mains, driven by three Otto gas-engines of a total of 100 effective horse-power. There was one peculiarity in the system which was very interesting. The gas-engines used were moderately large engines, but there was used to start these gas-engines a small Brotherhood hydraulic engine, worked with water pressure from the accumulators. A system of this kind was about to be established in Manchester, but from the local conditions there, the necessity of working by presses which were already constructed, and which the owners did not like to alter, they were going to use the enormous pressure of 1,600lb. per square inch. There was another peculiarity about the Manchester system, which touched on a point to which he would have to allude in his last lecture. At Manchester they had come to the conclusion that it would be economical to have a high-pressure hydraulic system and an electric lighting station worked from the same generating station. It came to be a case of improvement of load-line. They hoped to realise an economy from working a power system and a lighting system in conjunction.

Hydraulic Power Stations (Reservoir Storage), Zürich, Geneva.

He now came to consider the hydraulic transmissions at low pressure, in which there was no accumulator storage, but a reservoir storage. In connection with these low-pressure systems he would be driven to speak of high pressure and low pressure; that was in the characteristic examples he was going to quote there were comparatively low pressure and comparatively high-pressure mains. But high pressure meant only one third of the pressure of the London system.

The first of these foreign hydraulic transmitting systems which he wanted to describe was the one at Zürich. That installation

Hosted by Google

was a complex and very interesting one. It was the earliest system in Switzerland in which hydraulic power was used partly for the supply of potable water for town purposes, and partly for the supply of motive power from the same central station. It had grown gradually, and within the last three or four years had been very considerably extended. The system at Zürich now comprised a water supply for the town, the supply of motive power by wire rope to certain factories, the supply of motive power by low pressure water from the town mains, the supply of motive power by a special high-pressure system with about 500ft. head, and an electric lighting station. All these were under one management. Originally the water supply was obtained from a filter in the bed of the river Limmat, near its exit from the lake at Zürich. This water was pumped by turbines erected in the river a little further down. The quality of the water was found to be inferior; they had a bad outbreak of typhoid some years ago which led to an inquiry, and now the water for the supply of the town was obtained entirely from the lake itself, the main being extended a considerable distance into the lake, and the water from the old filter bed was now used entirely for motive power purposes. The pumping station had provision for 12 turbines, of which eight were Jonval turbines, of 80 H.P. each, and another of recent construction was of 175 H.P. The whole of the turbines worked on a horizontal shaft. The fall was 5ft. to 10½ft. The large double-acting pumps worked by gear from the shaft. There were two 300 H.P. compound steam-engines which were idle nearly all the year; they were held in reserve in case of some extraordinary low condition of the water when the power of the turbines would be insufficient. The electric lighting station was the next part of the central station. There were two alternating dynamos which could be driven in three ways. The normal way of driving them was by two impulse turbines of about 200 H.P. each, which were driven by water which had been pumped by the other turbines into reservoirs. The dynamos could also be driven off the horizontal shaft by the low-pressure turbines, or by the steam-engines. The power was obtained at Zürich, just as at Geneva, in this way: A weir was constructed across the river, and in the river was a longitudinal embankment. At the end of one of the two divisions of the river so formed by the embankment the turbine house was placed, and in the one division the water was kept up to a definite high level. The other half of the river was deepened by dredging and formed a means of discharging the surplus water and of taking the tail water from the turbines. At the head of the first division of the river there were moveable sluices by which in times when there was a great deal of water to be got rid of it could be got rid of down the arm of the river without interfering with the turbines or increasing the high level in the length. The power obtained from the turbines was distributed somewhat in this way: for pumping the town supply of water 240 E.H.P.; for the supply of motive power on the low-pressure system, about 130 H.P.; for the supply of motive power by rope transmission, about 230 H.P.; and for supplying motive power on the special high system, power which was chiefly used at present in the lighting station, 450 H.P. In connection with the pumping station they had at Zürich four reservoirs to which they could pump water at different elevations, varying from 154ft. above the pumping station to 530ft., the reservoir at 530ft. being the one which stored the water for the high-pressure hydraulic transmission system. For a horse-power for a year of 3,000 working hours they charged at Zürich from £7. 10s. to £16. The Zürich system had been working, with the exception of one part of it, for fifteen years or more.

Quite recently there had been established, very much on the pattern of the Zürich system, a still more important station at Geneva, where there was now in continuous daily operation one of the largest and most remarkable hydraulic power stations in the world. The water of the Rhone was employed to drive a series of large low-pressure turbines, and giving a total effective power of 4,500 horses. These turbines pumped water into two systems of mains; one, the older of the two, was termed the low-pressure system, the pressure being about 160ft. to 200ft. of head, 70-90lb. pressure, This was a development of a previously existing system, and was still chiefly intended to supply water for domestic and municipal purposes. The other system of mains was termed the high-pressure system, and had a pressure of 460ft. (200lb. pressure) of head at the pumping station. This system was partly intended to supply potable water in the higher parts of the town, which could not be reached by the low-pressure system; but it was specially intended for motive power purposes. Reservoirs had been constructed at Bessinges to supply this high-pressure system, and to store water pumped by the turbines at night and at times when other demands on the apparatus were scanty. The water pumped up to Bessinges, 460ft. above the pumping station, represented part of the water power of the Rhone, which without this storage reservoir would be wasted.

The Geneva system, it would be seen, was a complex one, which had been developed under special local conditions. In spite of natural and political isolation, manufacturing industries had for centuries flourished at Geneva. That they did so was partly owing to the fact that water power was easily obtained from the Rhone. The industrial quarter gathered along the two banks of the river, and factories at one time were built even in the stream itself. In 1871 Colonel Turrettini, the engineer under whose direction the present works had been constructed, had applied to the Town Council to place small-pressure engines on the mains of the then existing water supply. The plan of obtaining motive power in this way proved so successful and convenient that in 1880, before the new works were commenced, there were 111 small motors at work in Geneva, using 34 million cubic feet of water annually, and paying a yearly rental to the town of £2,000. The cost of the power at that time to consumers was at the rate of from £36 to £48 per horse-power per year of 3,000 working hours. Finally, in 1883, a contract was given to construct the works. The turbine house was constructed on the basis of the supply of nearly 4,500 H.P., and at present 3,500 H.P. was being developed. As in the case of Zürich, they proceeded by dividing the river into two parts. Partly by utilising the islands in the river, and partly by constructing a longitudinal embankment, they had divided the river into a head race to the turbines and a race for the discharge of the surplus water (*see* Fig. 3). The works altogether had cost £283,000. This included outside items, and the cost of utilising the forces of the Rhone was only £200,000. The turbine and pump-house placed at the end of the head race was originally intended to contain 20 turbines of 210 H.P. each. At present there were only 18 Jonval turbines, some of which were of more than 200 H.P. They worked on a vertical shaft, and a crank drove two double-acting pumps placed at right angles. The head varied from 5½ft. to 12ft. Great power, therefore, was obtained out of a very moderate fall. There was a special arrangement in the turbines by which variation of fall produced very little variation in the speed of the turbines. The original motors used were Schmidt pressure engines. These were still used for the smaller powers. They were very convenient, and very cheap, and could be run at any speed required by the machine to be driven. They acted as perfect meters of the amount of water used. In Geneva, for all except very small motors, impulse or partial admission turbines were used. The maximum efficiency of these was from 65 per cent. to 75 per cent., and not much less with light loads. They were cheap, occupied little space, and the speed was easily and perfectly regulated by a governor. In Geneva, the question of speed regulation was found to be a very important one. Industries connected.

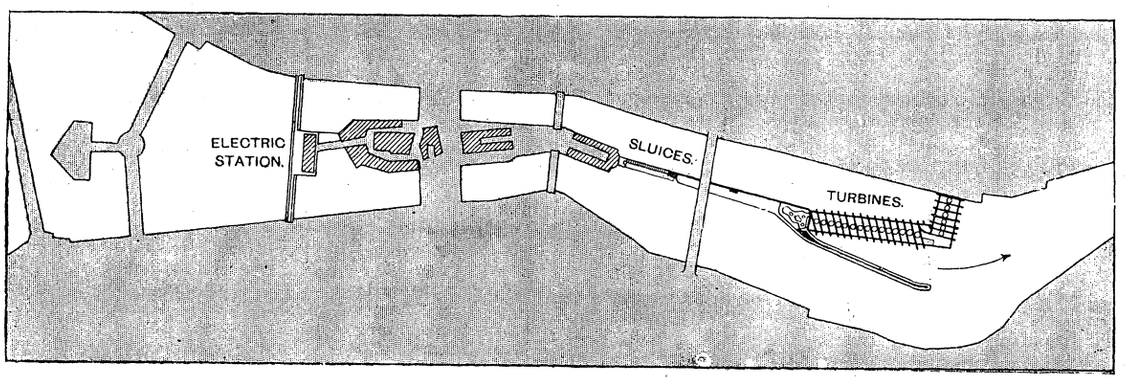

FIG. 3.—Geneva Hydraulic Works. Plan.

with watchmaking required motors with very great speed-regularity. To meet these conditions, MM. Faesch and Piccard had invented the relay governors, described in a previous lecture, and he might mention that a short time ago he found about 100 turbines in Geneva fitted with them. In Geneva there was hardly any intermittent machinery worked from the power system; the pressure water was almost entirely used for continuous working machines. The largest single amount of power which was used was that which was used in the electric station. There was one rather beautiful contrivance on the high-pressure transmission in Geneva, a contrivance so novel that he thought it might be interesting to describe it. The pipe-main from the town of Bessinges, four kilometres off, sometimes took water up to the reservoir and sometimes brought water back from the reservoir. There would be variations of pressure-head in the town, according as the water was being pumped up to the reservoir or being brought back from it. This would not be very serious if all the water applied for power purposes had been measured by ordinary meters. But in the case of some of the motors they charged for the pressure-water supply in this way: they had an orifice of a fixed size on the main, and they could take all the water they could get out of it during certain hours. On the power supplied in this way there would be a variation of 20 per cent. due to the variation of pressure. To obviate the variation of head there had been devised a centrifugal pump relay, which went into action and increased the pressure-head whenever necessary. The relay was placed one kilometre out of Geneva. There was first an impulse turbine, which drove the centrifugal pump; the whole of the water either going up to or coming back from the reservoir passed through this centrifugal pump, except in case of accident, when it could be carried straight through without going through the relay-house. When the water was going up to the reservoir the pump was stationary. The moment the water began to flow back from the reservoir, and a friction of 3 or 3½ kilometres of main arose, an automatic arrangement put the pump into action, and it acquired a speed proportional to the loss of pressure in the main, and it added to the pressure-head very nearly the equivalent of the loss. The whole arrangement was absolutely automatic.

In 1887 the City Council of Geneva entered into an arrangement with the Company for supplying electricity for lighting. It was part of this arrangement that the Company should use motive power supplied by the town for all its installations. Power was supplied to the Electric Lighting Company at the rate of £3 per effective horse-power per annum, and they now took from the Municipality turbines a maximum of 625 E.H.P. They had three 300 H.P. turbines and one 25 H.P. The £3 just paid the town for the cost of pumping the water, and the town had the right, first of all, to certain additional profits of the Company over a certain percentage, and secondly a right to buy the Company up after a certain number of years. At first sight that looked a very singular arrangement of having an electric light station worked by pumped water. At Geneva it was absolutely rational. The power taken in that way was power which was obtained from the Rhone by those primary turbines chiefly in the night time, when the power could not be otherwise used and would be wasted. The Electric Lighting Company there probably got the cheapest supply of power of any electric lighting company in the globe. He (the lecturer) was in that lighting station a year ago, and he never was in a station so quiet; there was nothing in the whole station you could hear, and nothing you could see moving excepting the governor balls of the turbines. The turbines were started instantly by the opening of the sluices, and once open the governor took care of them, and they wanted very little more attention. Of course, if the electric lighting station wanted to work continuously during the 24 hours it would be no longer economical to use the pumped water. But it only wanted to work for four or five hours in the evening, and therefore it was economical to work from the pumped water from the reservoir. The works at Geneva had been so entirely successful up to the present that they expected to have their whole 4,500 H.P. in full operation within five years. They were already deploring the fact that they would not have power enough even then, and were maturing plans for another power station about six kilometres below Geneva, where 12,000 H.P. would be delivered. That system would be on a different plan.

London and Geneva Systems Compared.

He would, in conclusion, make a comparison, from which he would leave them to draw a moral. They had in London an admirable system of hydraulic transmission, perfectly applicable to the purposes to which it was applied, successful in method of working, and he believed successful in financial working also. This reflected the greatest credit on the engineers of the Company who had had the courage to carry the system out. But the system, great as it was, was a limited one. In this enormous and busy metropolis the number of renters of power was under 2,000, and the power supplied was no more than 1,500 effective horse-power. In a comparatively small town, Geneva, with 1-80th the population of London, there were, three years ago, 137 motors, aggregating 280 H.P. on the low-pressure system, and 79 motors, aggregating 1,284 H.P. in daily and regular work on the high-pressure system. The use of the power was then increasing at the rate of 200 H.P. per annum. It appeared that in Geneva more power was daily distributed than in London. It was distributed in a form more adapted for ordinary industrial purposes without in any way being ill-adapted for the special purposes of lifting machinery, which was the chief object of the London system. Further, the power was distributed to consumers at about one-fifth of the cost at which it was distributed in London, for the special purpose of electric lighting it was distributed at one-twelfth the cost of the power distributed in London. There were in London 2,500 gas engines, which represented a power virtually distributed from central stations. It was not his intention to depreciate the efforts of English engineers, but it was well to recognise that, even if the gas engineers were taken into the reckoning, power was more easily and cheaply obtained in Geneva than it was in London. Local conditions had something to say as to that, but it might be that they had not yet adequately realised what an advantage cheaply distributed power was, or tried all possible means to secure so desirable a commodity.

LEGAL INTELLIGENCE.

The National Telephone Company (Limited) and Another v Graff Baker

JUDGMENT.

The judgment in the above action, a full report of which will be found in our issues for December 16th, 23rd, and January 20th, 27th, was delivered on Saturday morning last by Mr. Justice Kekewich:—

As between the National Telephone Company, whom I shall treat as the sole plaintiffs, although another is associated with them, and the Leeds Corporation, whom I shall treat as the real defendants, although not appearing on the Record, there is no question of title, and no question but that each is lawfully exercising undoubted rights; nor is there any question but that the acts of the defendants interfere with the exercise by the plaintiffs of their lawful rights. This would, I think, have been undoubtedly true if the case had been thrashed out on evidence without the advantage of Mr. Macrory's report, but that report renders it unnecessary to deal with the evidence on this point, and the interference is of a serious character, so that if actionable the remedy would properly be by injunction rather than by damages.

The real and only question in the case is whether the interference is actionable. It was practically admitted by the plaintiffs, and my own view certainly is that if they can maintain the action against the defendants at all, it must be on the application of the principle now well-known as that of "*Fletcher* v. *Rylands*." That principle, for the purpose of application to the case in hand, may conveniently be stated by reference to the second of four propositions set out in the fifth chapter of Mr. Garrett's book on the law of nuisance, which I have consulted in connection with more than one point in this case, and gladly take this opportunity of mentioning as a work of uncommon merit. I will read the proposition in the author's own words, but think it capable of improvement by the substitution for "non-natural" of "extraordinary," which is the term employed by Lord Kingsdown in defining somewhat analogous water rights in his well-known judgment in "*Miner* v. *Gilmore*," 12 Moore's Privy Council, page 131. The land into which the plaintiffs and defendants alike discharge their electric current does not belong to either of them, but for the reasons above indicated there cannot, as between them, be any question that the principle ought to be applied, if it be applicable at all, on the basis of their being absolute owners. That principle has never yet been applied in English law to such a matter as is now under consideration, and perhaps it would not be too much to say that those who enunciated the law in *Fletcher* v. *Rylands*, and have commented on and followed it in other cases, never had present to their minds the application of the doctrine to an electric current, and the possible consequences of its discharge into the earth. The question has been carefully considered in America, and I have studied with deep interest the case of *Cumberland Telephone and Telegraph Company* v. *United Electric Railway*, 42 "Federal Reporter," page 273. The judgment of the Court in that case, though in no wise binding on me, has commanded my earnest attention and respect, and, but for one circumstance, I should not hesitate to allow my own conclusion to be guided by the powerful arguments there set forth. That one circumstance is the want of full adoption of the principle of *Fletcher* v. *Rylands*. American law apparently holds the owner of land used for a non-natural or extraordinary purpose responsible for the consequences of such user to his neighbour only when they result from that owner's negligence, and if he can satisfy the Court that he has not been guilty of negligence, the resulting damage to his neighbour is not actionable. It seems to me that if the principle of *Fletcher* v. *Rylands* had been carefully adopted in America, the conclusion of the Court in the case just cited must have been different. I believe that in Scotland, too, the principle of *Fletcher* v. *Rylands* has not been accepted, and is not regarded as consistent with justice between man and man. It

Hosted by Google

does not fall to me to consider so large a proposition. The principle is thoroughly well settled here, and my duty is merely to consider whether it is applicable. It would be easy, of course, to point out differences between all the cases to which it has hitherto been applied and the present, and I have already said that injury arising from such a case as the discharge of electric current can scarcely have been contemplated by any judge in previous cases. But after reflecting much on the novelty of the case, on the arguments addressed to me, and on the peculiarity of an electric current as distinguished from every other power, I fail to see any reason why the principle should not be applied to it. I cannot see my way to hold that a man who has created, or, if that be inaccurate, called into special existence, an electric current for his own purposes, and who discharges it into the earth beyond his control, is not as responsible for damage which that current does to his neighbour as he would have been if instead he had discharged a stream of water. The electric current may be more erratic than water, and it may be more difficult to calculate or to control its direction or force; but when once it is established that the particular current is the creation of or owes its special existence to the defendant, and is discharged by him, I hold that if it finds its way on to a neighbour's land, and there damages the neighbour, the latter has a cause of action. At any rate, I think that if a distinction is to be taken between this and other forces for this purpose, that distinction must be made by a higher tribunal, and not by a judge of first instance. It was endeavoured to be argued on behalf of the defendants that the current injuring the plaintiffs was only part of the general body of electricity which may be now said to exist everywhere, and to be proceeding in every direction; but the effect of the defendant's operation is to collect a particular portion of this body and to discharge it into the earth at a particular spot, and there can be no doubt that the disturbance of the plaintiffs' telephone system is caused by the particular quantity thus discharged.

Assuming the action to be maintainable on the principle of *Fletcher* v. *Rylands*, the defendants rely on two answers to the plaintiffs' claim. First, they say that the plaintiffs might by an alteration of their system, that is by the adoption of what is known as the metallic return, prevent the disturbance complained of; and secondly, they say that the defendants are acting under statutory powers, and that if in the proper exercise of those powers they injure the plaintiffs they are free from blame. The first answer is, to my mind, without foundation. The man who complains of his land being thrown out of cultivation by the incursion of water escaping from his neighbour's reservoir must not be told that he has no right of action because if he had interposed a wall or otherwise taken care to protect himself the water would not have reached his land. He is using his land in a natural way, and is not bound to take extraordinary precautions, and is entitled to rely on his neighbour also using his land in a natural way, or, if he uses it otherwise, taking extraordinary precautions to prevent damage to others therefrom. There is no doubt a body of evidence to show that a system different from that adopted by the plaintiffs has been adopted elsewhere with advantage, and may possibly prove to be the most convenient though more expensive for them; but the evidence also proves that their present system has been largely adopted and is received with favour by many competent to form an opinion. It also has the merits of economy. They are carrying on their own business lawfully and in the mode which they deem best, and I cannot oblige them to change their system because they might thereby possibly enable the defendants to conduct their business without the mischievous consequences now ensuing. True it is that the analogy introduced above fails to this extent, that the plaintiffs are using the land for an extraordinary purpose; but admittedly it is a lawful purpose, and though under an obligation to obviate mischief from their own operations to their neighbours they are under none, in my judgment, to protect themselves from the defendants or others. The outflow from one reservoir might easily destroy another, but, so far as I am aware, there is no principle or authority in English law for rejecting a claim for damage by the owner of the latter on the ground that his user, as well as that of the neighbouring owner, is extraordinary.

The second answer of the defendants to the plaintiffs' claim has required more examination. Having recently had occasion in *Allison* v. *The City and South London Railway Company*, and again in *Rapier* v. *The London Tramways Company* to consider such a plea as is here put forward, and to consider many authorities, and in particular the cases of *The Metropolitan Asylum District* v. *Hill* and *London, Brighton and South Coast Railway Company* v. *Truman* and their application to different provisions and circumstances, I do not find it necessary again to state my view of the law or of the lines by which I ought to be guided in applying it to a particular case. Therefore, I shall but briefly explain the reasons for my conclusion that the defendants' plea is good in law, and that they are not responsible to the plaintiffs for the mischief caused by their works. The defendants' authority is derived under a Provisional Order confirmed by Act of Parliament. Such Provisional Orders in connection with tramways and many other undertakings of a public character are now common, and, I think, must be treated as "a well-known and recognised class of legislation" equally as much as the Railway Acts, which were referred to in those terms by the Lord Chancellor in *The London, Brighton and South Coast Railway Company* v. *Truman*, 11 Appeal Cases, page 53. The Railway Acts (again using the language of the Lord Chancellor in the same case) were assumed to establish the proposition that the railway might be made and used whether a nuisance were created or not, and, in my judgment, a like proposition must be assumed to be established by the Provisional Orders, one of which is here under consideration. The defendants are expressly authorised to use electrical power, and the Legislature must be taken to have contemplated it, and to have condoned by anticipation any mischief arising from the reasonable use of such power. A distinction was endeavoured to be made between cases where extraordinary powers are directly sanctioned by the Legislature and those where it is left to some other authority (in this instance the Board of Trade) to determine whether, if at all, they may be brought into operation. It is within the competence of the Legislature to delegate its authority, and when once that delegated authority has been properly exercised by the agent to whom it is entrusted, the sanction is that of the Legislature itself, just as much as if it had been expressed in the first instance in an Act of Parliament. The defendants relied on the 51st section of the Provisional Order. They argue that the exception there made in favour of the telegraph which would include telephonic lines of the Postmaster General indicates that interference with any other like lines was intended to be permitted. The reference supports the more general argument, and I have, therefore, mentioned it, but I rest my decision more on the established principle laid down in many of the cases, and ultimately ratified by the House of Lords in *London, Brighton and South Coast Railway Company* v. *Truman*.

To this plea of statutory power the plaintiffs have a rejoinder. They say that such power cannot avail the defendants unless they have acted reasonably in the exercise thereof, and have done their best to avoid injury to their neighbours. The argument being sound in law, one is compelled to examine the facts. The defendants work their tramways on what is called the single trolley system. There are other systems which have from time to time been used, and it seems are still in use elsewhere, and there are at least some good reasons for the conclusion that by the adoption of one or other of these systems the defendants might wholly or partially avoid the mischief which they now occasion. There is a contest on the evidence whether any of these other systems can be regarded as good apart from comparison with that of the defendants, and there is a further conflict of evidence whether if good they are comparable in merit with that of the defendants. My conclusion from the evidence is that the defendants' system is on the whole the best which practical science has yet discovered, but there is no occasion really to go as far as this. It is enough to say, and about this I entertain no doubt, that it is at least as good as any other, and has been proved by experience, especially in the United States, where there have been larger opportunities for experiment and consideration, to be as likely as any other to meet the requirements of traffic and the convenience of all concerned in the protection of the site of tramways for the use of legitimate purposes other than those of the tramway undertaking. It cannot be that in the application of the law which I am now considering the Court is bound to hold a railway or other company liable for the consequences of acts done under Statutory powers, because it has not adopted the last inventions of ever changing, ever advancing, scientific discovery. It is surely impossible with any regard to that common sense which after all is the foundation of this and many other branches of law to say that a railway which was not liable last year, last month, or even yesterday, because until then its undertaking was carried on according to rules acknowledged to be the best, is liable now not because those rules have been proved to be altogether wrong in practice, or unscientific in principle, but because some diligent worker in this department has discovered what is held for the moment to be a large improvement, but may to-morrow turn out to be only a step in the progress of further advance; and yet this might be the necessary conclusion in many cases, and indeed might be the necessary conclusion here if I were driven to support the plaintiffs' claim on the ground that the single trolley system, so largely approved where it has been largely tried, does not avail the defendants as a proper exercise of their statutory powers because another system is in use and apparently successfully used at Buda Pesth or elsewhere. I do not wish to prejudice the question whether a charge of negligence in the exercise of statutory powers can be supported by cogent evidence that the company exercising those powers has failed to adopt alterations or precautions which sufficient experience has shown to be of large indisputable and permanent value. That question may easily arise in many of the disputes which are likely enough from time to time to occur between public companies and those whom their operations injuriously affect, and it may even arise between the parties to this litigation. Suffice it to say that it does not arise now.

Holding on the above grounds that the plaintiffs cannot maintain an action either for an injunction or for damages against the defendants, I must order them to pay the general costs. If ever there has been or can be a case to which the distinction between the two scales of costs is properly applicable, this is the one, and the costs must be taxed on the higher scale. But it remains to make an exception, and that of some extent. I have already stated that the interference with the plaintiffs by the defendants is beyond doubt. I do not think that this ought to have been litigated. Mr. Macrory's report shows that one fair experiment would have proved the facts about which there was really very little doubt independent of his report, and that much time was uselessly spent on evidence. Not only must the plaintiffs be excused payment of the defendants' costs of this issue, which must be defined to be the issue whether the plaintiffs' telephonic system was in fact interfered with by the defendants' operations, but the costs thus excepted from the general costs of the action must be borne by the defendants and set off. Those costs will, of course, include those incurred in the experiment conducted at Leeds under Mr. Macrory's superintendence. They must also include the fee payable to Mr. Macrory, which it was agreed I should settle. I have communicated with him, and ascertained the time occupied and also the expenses incurred by him in railway journeys and the like, including the expenses of the gentleman, Mr. Cuninghame, whom he asked to assist him; and taking into consideration these items, I have fixed his fee at 50 guineas to cover all expenses, and also such fee as he thinks fit to pay to Mr. Cuninghame. I am glad to think that the course pursued with the concurrence of both parties of sending him down to make experiments and report was not only successful in finally settling an issue of fact, but also shortened the trial, and saved the further costs which further dispute on this point would necessarily have involved.

There will be judgment for the defendants, with costs modified in the manner above expressed.

AMERICAN NOTES.

(FROM OUR OWN CORRESPONDENT.)

NEW YORK, *Jan.* 27, 1893.

The Incandescent Lamp Question.—As outlined in our last week's letter, the General Electric Company seems to have thoroughly defined its position in regard to the incandescent lamp. In pursuance of this policy it has instituted a suit for an injunction against the Beacon Vacuum Pump and Electrical Company of Boston, to prevent its further manufacture of incandescent lamps in violation of previous decisions of the Courts. It was supposed that this suit would take the ordinary course through which the others had gone, and that an injunction would be at once granted, but a surprise was in store for everybody in the stand which that Company took. They introduced testimony and exhibits to prove that one Henry Goebel, a German by birth, had made and used sometime in the eighteen fifties an incandescent lamp embodying the same features, which nearly 20 years afterwards were covered by Mr. Edison's American patents. It seems from the affidavit of Goebel that he used an all-glass globe with platinum leading-in wires and an attenuated filament of carbonised bamboo, arranged in various shapes, among which were the hairpin or horseshoe form, and that he exhibited these frequently at night on the streets of New York. The daily papers, as well as some of the electrical journals, have committed themselves to the statement that Edison was certainly anticipated by Goebel, but these announcements appear to be premature. The General Electric Company claims that the testimony offered in this case was at hand, and known to each of the previous defendants in similar suits, but was by them regarded as of so little importance as to be unworthy of presenting. Prof. Elihu Thomson testified that he was aware of Goebel's work 10 years ago, and that he at that time examined the lamps, and was not impressed with their importance. The case was lately argued on both sides, and occupied the first half of the week. The judge reserved his decision, however, requesting both sides to present their arguments in type by Wednesday, February 1st, at 4 p.m., when he would take the matter into consideration, and give judgment later. The general feeling seems to be that the injunction will eventually be granted, for the burden of proof lies with the defendants. The three exhibits of the Beacon Vacuum Pump and Electrical Company were all of the same type of lamp, and showed leading-in wires and filaments as described, but in all cases the lamps were broken, so that there was no longer a vacuum. It is claimed that these three lamps were lamps made previous to 1860, but it remains to be proved that they are the same identical lamps. However, this withholding of judgment has placed the lamp industry in a very peculiar position. No more suits can be inaugurated until after this decision is rendered, before which time, in all probability, several weeks must elapse. In the meantime those lamp manufacturers who have been enjoined by the General Electric Company are turning over their orders to the other lamp manufacturers that have not been enjoined, and who for the time being are doing an enormous business in the sale of lamps which before had little or no market value. The inevitable result will be to bring the industry into disrepute, and to create such an unsettled condition of the market that it will seriously embarrass the whole industry.

CORRESPONDENCE.

USEFUL FORMULÆ.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: As Prof. Forbes has called attention to several approximate rules, the following one, for finding the current in a long straight wire, may prove of interest.

Let the wire be placed parallel to the magnetic meridian, and a small watch-charm compass be held vertically over or under the wire and moved nearer to or farther from it until the deflection is 45deg., then the distance of the compass needle from the wire in centimetres multiplied by 0·9 gives the current in amperes passing in the wire. If, instead of 45deg., a deflection of 48deg. is taken it is not necessary to multiply by 0·9, but the distance in centimetres is approximately equal to the current.

Of course, only very rough results can be obtained, as to make the above rule strictly accurate the wire should be infinitely long; but, as a rough-and-ready method of getting an idea of the current in a conductor, it may prove of service.—Yours, &c., E. C. RIMINGTON.

Lynton House, The Park, Norwood, S.E.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: I should like to add to Prof. George Forbes' "useful formulæ" a rule I have found very handy for calculating resistances of mains, &c. It is as follows:—

A copper rod, 1 foot long, and having a sectional area of 1 square inch, has a resistance of 0·000008 ohm. This is for pure copper, hard drawn, at a temperature of about 50°F.

The resistance of any wire can be easily found by multiplying the number 0 000008 by the length in feet and dividing by the sectional area in square inches. The above rule is sufficiently accurate for calculating roughly the resistances of mains; but for dynamo and transformer work the result obtained should be increased by 10 per cent.—Yours, &c.,

J. A. KINGDON.

29, Marlborough-hill, N.W., February 6, 1893.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: Allow me to add to the useful formulæ which appeared in last week's *Electrician*.

A horizontal belt, 1in. wide, running at 10ft. per second (600ft. per minute), will transmit 1 H.P. if the pulleys are not too small. A proportional increase of width at the same speed, or a proportional increase of speed of a belt the same width, will transmit a proportional increase of power.—Yours, &c., J. H. GREENHILL.

New King-street, Belfast, Feb. 7, 1893.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: To Prof. Forbes's list of approximate formulæ, I may add the following convenient method of finding the capacity of water pipes and cisterns.

A pipe, *one* inch in diameter, holds *one* pound (or 0·1 gallon) of pure water in *one* yard run, so that the capacity of any pipe for the length given may be represented by its sectional area in inches. If greater accuracy is required, the result must be increased by one-fiftieth.

To find the capacity of a cistern, it is only necessary to remember that eight cubic feet contain 500lb., or 50 gallons, of water, this being a trifle over half a pound in excess of exact measurement.—Yours, &c., N. G. THOMPSON.

13, Victoria-street, London, S.W.,
February 8, 1893.

ELECTRIC LIGHTING IN THE WEST END.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: With reference to certain letters which have appeared recently in the Press on the subject of the cost of Electric Lighting in the West End, I beg to inform you that my Company has decided to reduce the standard price for the supply of electricity to all their customers from 7d. to 6d. per Board of Trade unit. Customers will further have the benefit of a sliding scale of charges extending from 6d. to 5d. per Board of Trade unit, based on the amount of electricity consumed in each case.—Yours, &c., F. J. WALKER,

General Manager and Secretary.

The St. James' and Pall Mall Electric Light Company (Limited), February 8, 1893.

The Marseilles-Tunis Cable.—The 725-mile cable which is being laid down between Marseilles and Tunis is the second which has been made in France.

TRADE NOTES AND NOTICES.

Our readers are reminded that the 1893 Edition of "THE ELECTRICIAN" Electrical Trades' Directory and Handbook is NOW READY. This useful book contains over 1,000 pages, and several new and handy features have been added. The price of the Directory and Handbook is 7s. 6d. Postage in the United Kingdom, 9d.; abroad, 1s. 4d.

TENDERS INVITED.—The Corporation of the City of Londonderry invite tenders for the supply and erection of steam boilers, steam engines, condensers, steam and water pipes, water tanks, electrical machinery and apparatus, arc lamps, lamp pillars, underground mains, &c., for lighting the streets by electricity. Some particulars are given in our advertisement columns, and plans and particulars have been prepared by Mr. H. W. Blake, engineer to the Corporation, and can be obtained at the Guildhall, Londonderry. Tenders must be sent in to Mr. R. N. Chambers, town clerk, not later than March 1st next.

——— The Directors of the Great Western Railway Company invite tenders for the supply of 60,000 electric light carbons. Specifications and forms of tender can be obtained of Mr. G. K. Mills, secretary, at the Paddington Station, or of the Stores' Superintendent, at Swindon. Tenders must be addressed to the secretary, at Paddington Station, on or before Wednesday, March 1st.

——— The tenders required by the Corporation of Nottingham for the supply and erection of boilers at the electric lighting station in Wollaton-street must be sent in by February 16th.

——— The Corporation of Warrington invite tenders for the erection of telephones and wires to connect the two intercepting depôts at Howley and Hardy-street with the depôt at Longford. Tenders to be sent in to Mr. J. Lyon Whittle, town clerk, by the 14th inst.

——— The Municipal Authorities of Ployesti, Roumania, invite tenders, which will be received until March 10th next, for the concession for the electric lighting of the Town for a period of thirty years.

TENDERS ACCEPTED.—The tender of Messrs. Lowden Brothers, of Dundee, for lighting the Town House by electricity has been accepted, the amount being £79. 15s. The installation is to consist of 89 16 c.p. incandescent lamps.

——— The tender of Mr. G. Jennings, of Lambeth, London, S.E., has been accepted for an installation of Jennings' and Brewer's electro-mechanical apparatus for the engine house at the pumping station of the Suffolk County Asylum at Melton.

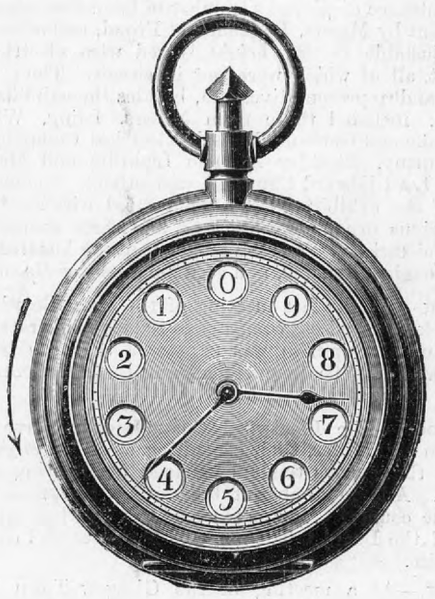
——— The Water Committee of the Plymouth Corporation have accepted Mr. Francis Dagger's tender for the renewal of their telephone line between Hartley and Roborough.

VACANT APPOINTMENT.—The Bolton Corporation are prepared to appoint an electrical engineer to take charge of the construction of the works in connection with their electrical installation, and to manage such works when completed. The salary will commence at £200 per annum. Mr. R. G. Hinnell will receive applications up to February 22nd.

BLOCKLEY ELECTRIC LIGHTING AND MANUFACTURING COMPANY (LIMITED).—This firm have just completed the lighting of the town house of the Hon. Mr. Justice Kekewich, in Park-crescent, Portland-place, W. The fittings (some of which are of special design) were supplied by Messrs. W. S. Benson and Co. and Mr. Richard Crittall.

"STANDARD" TUBULAR SYSTEM OF WIRING.—Messrs. Bagshawe Bros and Co., of Upper Thames-street, E.C., send a fully illustrated description of this system of wiring for electric lighting installations inside buildings. The tubes are made of "successive layers of a special 'papier-maché' thoroughly impregnated and coated with special insulating composition, which is insoluble either in water or acids—it is," according to the description, "therefore damp-proof and is not liable to chemical decomposition." The system seems to resemble that of the "Interior Conduit System" well-known in the United States. In many situations such tubes would be preferable to wood casing; but this is so dear to many fire office inspectors that the suggestion is likely to meet with opposition. Some reliable tests of the insulating properties of these tubes after exposure to damp for a week or two would be interesting. Several advantages are claimed for this system, including high and lasting insulation, compactness, easy fixing, and economy in comparison with other systems. The list includes instructions for making joints, &c.

MAY'S PATENT WATCH-SHAPE REVOLUTION COUNTER.—Where machinery is running it is often necessary to determine the number of revolutions, and there is a want for a portable instrument for this purpose, which does not easily get out of order or damaged by rough handling, and which can be easily read by anybody in the engine-room. May's revolution counter has been constructed to meet this demand. It takes the form of a pocket-watch, and is, therefore, conveniently portable. The watch-case keeps the works protected and clean, and to secure an easy reading the face is silvered and the figures are bold and black. The revolutions read off a dial like that of a watch by two arbors, the long one reading units and tens, the short one reading hundreds. The instrument is so constructed that whichever way the machinery revolves—to the right or left—it is direct reading. There is a disc under the face with a double set of figures, and these figures become visible through the apertures in the face automatically, in accordance with the direction in which the spindle revolves. The figure shows the spindle turning to the left, but the instrument



works automatically in either direction. By a key inside the back cover both arbors are easily placed back to zero. Messrs. O. Berend and Co., of 61, Fore-street, E.C., are the owners of the English patents.

BRIGHTON.—The Electric Lighting Committee of the Town Council have been asked to make arrangements, while installing the electric light on the Parade, to adopt such a system as will enable the light to be increased or decreased according to the state of the weather and the time of year.

BRISTOL.—As stated in a previous issue, Messrs. Siemens Brothers and Co. (Limited) have secured the tender for supplying the cables and laying the mains for the electric light installation of Bristol (subject to the confirmation of the contract by the Council). A sub-contract for the trenches and laying the cables has been given to Mr. Krauss, of Bristol. More than five miles of mains have to be laid, and the work is to be completed by the end of June.

BURTON.—The Health Committee of the Town Council in their last report recommended that advertisements be issued inviting tenders for the electric lighting of the district. The report was adopted.

DOUGLAS, ISLE OF MAN.—An action has been commenced in the High Court of Justice, Douglas, by the Brush Electrical Engineering Company (Limited) against the Douglas Grand Hotel, Theatre, and Baths Company (Limited), to recover £305. 11s. 3d., the balance of an account due for supplying the electric light to the defendants' premises. A delay of a week has been granted to enable the defence to be prepared.

DUNDEE.—The design of the street lamps selected for the public lighting of this City is similar to that of those supplied for the City of London lighting. The lamps will be 18ft. high to the lantern, and the columns will be inserted 4ft. into the ground.

EDINBURGH.—The Electric Light Committee of the Town Council decided on Saturday to take further professional advice before coming to a decision as to whether the Corporation should themselves undertake the work under the Provisional Order, or should hand it over to a company.

EDMONTON.—Mr. Coote, of Edmonton, has been appointed contractor for supplying the electric light to the Strand Workhouse and Schools situated at Edmonton.

Hosted by Google

ELECTRICAL EXHIBITION AT WINDSOR.—A successful electrical exhibition was held at the Albert Institute, Windsor, last week, under the auspices of the Windsor and Eton Scientific Society. The energy for producing the light and for operating machinery in motion was supplied by the Windsor and Eton Electric Light Company from their station about half a mile distant from the hall, Mr. Sevenoakes, the secretary, assuming the general superintendence, Mr. Hawkings, the Company's engineer, being in charge of the station. The current varied between 90 and 95 amperes at a voltage of 100, and the service proved very satisfactory. The exhibits were contributed by members and friends of the Society, and by electrical manufacturing firms. At the entrance to the building were suspended two of Messrs. Paterson and Cooper's 1,000 c.p. arcs, two smaller arcs being shown inside, and the main hall was illumined by electroliers and bracket lamps. A stand near the entrance displayed a number of handsome electroliers and brackets lent by Messrs. Benham and Froud, and a brass shaving-stand, adjustable to any height, fitted with electric lamp and attachment, all of which were put in circuit. The exhibits were numerous and representative, and, besides the exhibits previously mentioned, included those from Messrs. Laing, Wharton and Down, Drake and Gorham, Walsall Electrical Company, the Electrical Company, Blockley Electric Lighting and Manufacturing Company, Lord Edward Churchill, and others. Among the special features of the exhibition was a room fitted with an 11-light electrolier, various ornamental brackets, and some cooking apparatus heated by electricity. A small model working installation consisting of gas engine, dynamo, and accumulators was also shown.

EXMOUTH.—At the last meeting of the Local Board it was proposed to ask the local gas company to reduce their rates for public lighting, and the opinion was expressed that the gas company could not afford to be independent now that the electric light was obtainable on favourable terms.

FLEETWOOD.—The Fleetwood Commissioners have received a report from Mr. Miller, their consulting electrical engineer, on the subject of the various tenders received for lighting the town by electricity. A large number of tenders had been received from all parts of the country. It was resolved to refer these to the general meeting of the Board. The name of the successful contractor did not transpire.

GLASGOW.—At a meeting of the Glasgow Town Council, on Thursday, Mr. Burt said that as far as the works were concerned they were progressing satisfactorily, and they were now in a position to supply any number of regular customers with the incandescent light. With regard to street lighting, he expected that before the end of a month they would be in a position to light some of the principal streets.

GLOUCESTER.—The question of the lighting of the City was before the Gloucester Corporation last week, and one of the members of that body gave it as his opinion that "there was a brilliant future in store for gas, and that it would never be superseded by the electric light." We regret being unable to give this gentleman's name. No resolution was, however, moved on the subject.

HASTINGS.—At the last meeting of the Town Council, a resolution was agreed to, that it was desirable to light the Town Hall and the Brassey Institute by the electric light; the matter was referred to the Public Lighting Committee for their consideration and report.

HECKMONDWYKE.—At the last meeting of the General Works Committee of the Board of Health the consulting engineers invited to inform the Committee the terms upon which they were prepared to report and prepare specifications for the proposed lighting were present. A discussion took place on the general subject of lighting, and it was finally agreed that a poll of the ratepayers be taken as to whether the electric light should be introduced or not. The result of the poll is not to hand.

LLANDUDNO.—The Board of Commissioners were invited last week by Mr. John Smith to witness the installation of the electric light which has just been completed at his mansion at Craigside. In congratulating the host on his enterprise in electrical matters, the Chairman of the Board stated that the Committee appointed to inquire into the subject of the electric light and electric traction at Llandudno were giving the matter earnest consideration, and they would probably shortly ask the Board to sanction an installation of some magnitude.

MALVERN.—In reply to one of its members, the Clerk to the Local Board, at the last meeting, stated that unless the Board proceeded to use the powers they had obtained under the Electric Lighting Act, the Board of Trade could cancel the order; but he saw no reason why the Local Board should move in the matter at present. If any proposal was made by a private company for supplying the town with the electric light, the Board would then have to consider their position.

NANTWICH.—At the last meeting of the Local Board, the Chairman of the Electric Lighting Committee announced that that body had discussed various matters, including the advisability of the Committee being supplied with one of the electrical journals. The Chairman said that as it was an invarable rule for the various Boards and Corporations throughout the country who had appointed Lighting Committees to take *The Electrician*, the Committee recommended that this journal be supplied, which was agreed to.

PORTSMOUTH.—The report of the Electric Lighting Committee was discussed and adopted by the Town Council at their meeting on Tuesday, the 7th inst. The Committee submitted the tenders received for the three sections of contract No. 2 in connection with the electric lighting scheme, Section 1 comprising boilers, engines, &c., Section 2 dynamos, transformers, &c., and Section 3 turbine alternators.

Daniel Adamson and Co.	16,050	—	—	—
Julius G. Neville and Co.	Not on form of tender.			

The Committee considered carefully the whole of these tenders, although some of them were variations from the specification, and the whole of the tenders were referred to the engineers for their consideration and advice. The Committee were at first disposed to recommend the acceptance of Messrs. Yates and Thoms' tender for Section 1, that of the Electric Construction Corporation for Section 2, and that of Messrs. Parsons and Co. for Section 3; but it will be seen that Messrs. S. Z. de Ferranti and Co. submitted an alternative tender for direct running plant, which provided, however, for a much larger output than had been contemplated, and they submitted a proposal for a reduction in the plant and a co-operation with Messrs. Yates and Thom, as the makers of the engines and boilers proposed to be recommended, which appeared to offer many advantages. This proposal was therefore further considered, and the engineers were again consulted, and they pointed out that there were many advantages which would accrue from the adoption of the latter suggestion. Under it the total price for Sections 1 and 2 would be £21,780, and it would therefore be seen that this sum was £434 below the total of the lowest tenders for Sections 1 and 2, apart from the question of whether the joint tender would be more advantageous in other respects. The engineers, however, reported that there would also be great economy in space in the engine room, a reduction in the number of machines requiring supervision, a considerable saving in fuel, an increased output at present, and a saving in capital upon the tenders which it was at first proposed to recommend of £1,152. Under these circumstances, and bearing in mind the advantages which, as stated, would accrue from the tender of Messrs. Yates and Thom and Messrs. S. Z. de Ferranti and Co. for Sections 1 and 2, the Committee recommended that such tender be accepted at £21,780. The Committee also recommended that the tender of Messrs. Parsons and Co. for Section 3 be accepted at £1,750. The Committee further submitted a certificate from Messrs. Waller and Manville for payment to the contractor for the erection of the electric lighting station in Gunwharf-road of the sum of £240, on account of the work executed, and recommended that such amount be paid. As already mentioned, the Committee's recommendation was adopted.

ROCHDALE.—The decoration of the Town Hall having been completed, a suggestion has been made that the electric light should be adopted in order to protect these costly decorations, and that the river weir, on the Rochdale Corporation's estate at Roach Mills, should be utilised for power.

Hosted by Google

ST. GILES, BLOOMSBURY.—The clock of the St. Giles' Workhouse, Broad-street, Bloomsbury, W.C., is to be lighted by electricity at a cost of £150.

STAFFORDSHIRE.—At the last County Council meeting the Chairman notified that the electric lighting installation at the Werrington Industrial School had been started, and with excellent results.

SUNDERLAND.—At a special meeting of the Highways Committee of the Corporation last week it was reported that replies had been received from six consulting engineers regarding the terms upon which they were prepared to report for the proposed electric lighting of the Borough. It was ultimately decided to make still further inquiries.

TAUNTON.—Electricity has been used for about five years for blowing the organ at St. John's Parish Church, but notice has been received by the churchwardens from the Electric Lighting Company to the effect that after next month no more power can be supplied.

THE TEMPLE.—It is stated that an attempt is to be made to overrule a decision come to by the Honourable Society of the Middle Temple some time back, by which the installation of the electric light was rejected. A number of the residents in the Temple are, we understand, anxious to have the light, and are agitating for a lighting station to be erected in the grounds.

WAYLEAVES.—Three wiremen were brought up before the magistrate at the West London Police-court last week, charged with obtaining admission to the residence of Earl Poulett by false representation. It transpired that, owing to the difficulty of obtaining access to the roofs of private houses, the men had represented they were in the employ of the District Messengers Electric Service Company, which statement was untrue. The excuse given was the great difficulty experienced in running wires for private telephone installations. The accused were discharged with a caution.

COMPANIES' MEETINGS & REPORTS.

Liverpool Overhead Railway Company.

The following brief report of the Directors of this Company to December 31st last is to be submitted to the ninth half-yearly general meeting of the shareholders, to be held at the Law Association Rooms, Cook-street, Liverpool, on Tuesday next, the 14th inst., at three o'clock :—

The Directors report the approaching completion of the undertaking. The Marquis of Salisbury formally opened the line on the 4th inst., and it is hoped that in about a fortnight from that date it will be opened for public traffic. The preliminary trials have been very satisfactory, and the Directors believe that their anticipations, as to the efficiency and economy in working, will be realised.

To complete the present undertaking, and to provide for the cost of the Northern Extension, your Directors have issued 7,500 Five per Cent. £10 Perpetual Preference Shares, which were fully subscribed.

The Directors retiring by rotation at this meeting are Sir W. B. Forwood and Mr. Harold Brocklebank, and, being eligible, offer themselves for re-election. The auditor retiring by rotation is Mr. J. S. Harmood Benner, who is also eligible for re-election.

The report is followed by a statement of accounts and auditors' report.

Kensington and Knightsbridge Electric Lighting Company (Limited).

The following report is issued by the Directors of this Company, which will be presented at the sixth ordinary general meeting, to be held at 1, Great George-street, Westminster, S.W., on Thursday, the 16th inst., at five o'clock :—

The Company's mains, which extended for a length of 12½ miles in the previous year, have been increased during the year 1892 to 13 miles, and many of the existing mains have been increased in sectional area. During the year the number of houses and shops connected with the system has increased from 436 on December 31, 1891, to 550 on December 31, 1892; while the number of lamps calculated on the usual basis of 8 c.p. has increased from 38,408 to 47,441. The improvement in the efficiency of working the plant reported as being made at the last meeting has been maintained throughout the year.

In view of the increase in the business of the Company from the present district and in contemplation of the increase from the area mentioned in the next paragraph, the plant at Kensington-court and at Chapel-place has been extended, and further machinery is on order.

Negotiations are pending, and, subject to the approval of Parliament, may be regarded as practically concluded, for the transfer to this Company of that portion of the parish of St. Mary's Abbotts Kensington, which is at present served by the Chelsea Electricity Supply Company (Limited). The transfer cannot be carried into effect without the sanction of Parliament, and the necessary Bill has already been approved by the shareholders in two successive meetings, and has been introduced into Parliament. This transfer, if sanctioned, will add to the Company's area of supply an important district, which, in the opinion of your Directors will materially improve the Company's position.

The dividend on the Six per Cent. Preference Shares was duly paid to June 30, 1892, and an Interim Dividend at the rate of 4 per cent. per annum was paid on the Ordinary Shares for the first half of the year, and out of the balance standing to the credit of the net revenue for the year 1892, £3,792. 13s. 5d., the sum of £1,462. 10s. 0d. has been appropriated for the payment of the Preference Dividend to the end of the year, leaving £2,330. 3s. 5d., out of which it is proposed to pay a further dividend on the Ordinary Shares at the rate of 4 per cent. for the past half-year leaving a balance of £867. 13s. 5d.. It will be observed that no provision has been made in Accounts for Directors' remuneration.

In accordance with the Articles of Association, Mr. G. H. Hopkinson and Mr. Granville R. Ryder, retire from the directorship, and, being eligible, offer themselves for re-election. The auditors, Messrs. Lovelock, H. W. Whiffin and Dickinson, offer themselves for re-election.

India Rubber, Gutta Percha, and Telegraph Works Company (Limited).

The following is the Directors' report for the year ending December 31st last, to be presented at the twenty-ninth ordinary general meeting of the shareholders at the Cannon-street Hotel, E.C., on Tuesday, the 14th inst., at 12 o'clock :—

The accounts show the net profit for the past year to be £99,161. 11s. 7d. Adding £42,073. 5s. 10d. brought forward, and £43,110 premium on 8,400 new shares issued in March, and deducting £25,000 interim dividend paid in July, there remains a disposable balance of £159,344. 17s. 5d. Of this balance the Directors have added to the reserve fund £75,000 (including the premium on new shares), and recommend the distribution of a dividend of 10s. and a bonus of 5s. a share, free of income tax, amounting to £37,500, making, with the interim dividend, a total payment for the year of 12½ per cent., and leaving £46,844. 17s. 5d. to be carried forward.

The Company's ordinary business continues satisfactory. The principal cable work of the year has been the completion of the manufacture and the laying of about 2,200 miles for the South American Cable Company, and the manufacture of about 2,600 miles for the Central and South American Telegraph Company. The steamship "Silvertown" sailed on the 22nd of last month to lay the latter cable between Peru and Mexico.

The works and machinery at Silvertown and at Persan-Beaumont are in the usual state of efficiency.

Mr. S. Wm. Silver and the Hon. Henry Marsham, the Directors retiring by rotation, offer themselves for re-election. Mr. J. Weise, of Messrs. Turquand, Youngs, Weise, Bishop, and Clarke, retires from the auditorship; but Mr. J. F. Clarke, of the same firm, offers himself for election in his place.

CITY NOTES, &c.

BRUSH ELECTRICAL ENGINEERING COMPANY (LIMITED).—The Directors have declared an interim dividend at the rate of 6 per cent. per annum on the preference shares, and at the rate of 5 per cent. (the maximum allowed as an interim dividend) on the ordinary shares of the Company, for the six months ended December 31, 1892, payable February 27, 1893. The transfer books will be closed from the 15th to 28th inst. In view of the interest payable March 1st on the Debenture Stock of the Company, the transfer books of this Stock will be closed from February 20th to March 2nd.

CITY AND SOUTH LONDON RAILWAY COMPANY (LIMITED).—The traffic receipts for the week ended February 5th were £956, as against £824 for the corresponding period of last year, being an increase of £132. The total receipts for half-year amount to £4,910, against £4,152 in the corresponding period of 1892, being an increase of £758.

CUBA SUBMARINE TELEGRAPH COMPANY (LIMITED).—At a meeting of the Directors, on Wednesday, the audited accounts for the half-year to December 31st were submitted, and it was resolved, after providing for the interest on the Preference shares, to recommend the payment of a dividend on the Ordinary at the rate of 8 per cent. per annum, free of income tax. —The estimated traffic receipts of this Company for the month of January were £3,800, as compared with £3,518 in the corresponding month of last year.

DIRECT SPANISH TELEGRAPH COMPANY (LIMITED).—The traffic receipts for the month of January were £1,901, against £2,195 for the corresponding period of last year.

EASTERN EXTENSION, AUSTRALASIA AND CHINA TELEGRAPH COMPANY (LIMITED).—The traffic receipts of this Company for the month of January, 1893, amounted to £43,040, and to £42,805 in the corresponding period of 1892, or an increase of £235.

GREAT NORTHERN TELEGRAPH COMPANY.—The traffic receipts of this Company for January amounted to £20,800. In the corresponding month of 1892 and 1891 the amounts were £20,000 and £20,800 respectively.

TELEGRAPH CONSTRUCTION AND MAINTENANCE COMPANY.—Subject to audit, the Directors of this Company propose paying a dividend of 10 per cent. (£1. 4s. per share) in addition to the 5 per cent. already paid, making 15 per cent. for the year 1892.

WEST INDIA AND PANAMA TELEGRAPH COMPANY (LIMITED).—The receipts for the two weeks ended January 31st were £3,046, as compared with £2,727 for the corresponding period of last year.

Hosted by Google

WESTERN AND BRAZILIAN TELEGRAPH COMPANY (LIMITED).—The traffic receipts for the week ended February 3, 1893, after deducting 17 per cent. of the gross receipts payable to the London Platino-Brazilian Telegraph Company (Limited, were £3,559.

YORKSHIRE BOILER INSURANCE AND STEAM USERS' COMPANY.—At the twentieth annual meeting of this Company, held at Bradford recently, a dividend of 7½ per cent. was declared, and £1,090 added to the reserve fund, and the carry forward was £164. 13s. The chairman stated that 94⅓ per cent. of the whole of the boilers insured had been examined, and he was able to report that no explosion had occurred to any boiler under the Company's care since its formation.

INSULATORS
FOR
ELECTRIC LIGHT MAINS

For GLASGOW, PRESTON, DUNDEE, WESTMINSTER, ST. PANCRAS, &c.

Largest Stock of Insulators, Leading-in Tubes, Battery Jars, Porous Cells, Switch and Fuse Blocks, Plumbago Crucibles, Chemical Apparatus, &c.

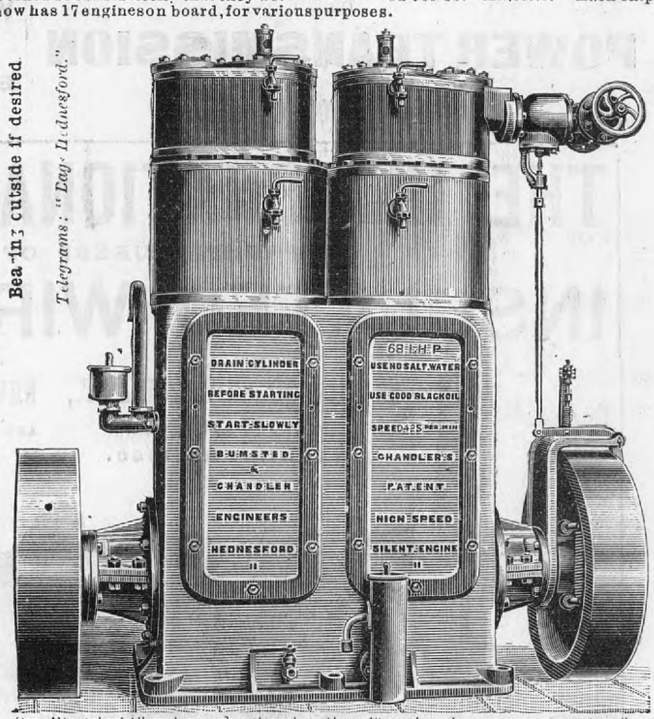
"SILENT" ENGINES (CHANDLER'S PATENTS)
FOR ELECTRIC LIGHTING.

Made in **20** SIZES, with one or two cranks, from 2 to 200 Horse-power, **simple compound or tri-compound, giving the highest economy,** at speeds suitable for coupling direct to dynamos for THEATRE-LIGHTING, for CENTRAL STATIONS, for SHIP-LIGHTING, and TRAIN-LIGHTING.

Electrical Firms and Shipowners may place perfect confidence in these Engines, as they are the most durable ever introduced, and as economical as any other high-class engine. After prolonged and severe tests (which caused the engines of other makers to break down) these engines were selected for use on ss. "*Teutonic*"; these worked so satisfactorily that they were also selected for ss. "*Majestic*." Each ship now has 17 engines on board, for various purposes.

Bearing outside if desired

Telegrams: "Day, Hednesford."



One Electrical Firm has ordered no less than 40 engines in two years, another firm 32, another firm 19, another firm 16, another firm 14, and a large number of other firms have sent many repeat orders. Twenty of the British India Steam Navigation Company's Steamers are lighted by these Engines. All this goes to prove that the Engines are reliable and highly satisfactory. Many are working without lubrication to Cylinders. **NO AIR NOR OIL CAN POSSIBLY PASS AWAY TO CONDENSER.**

Every part can be got at comfortably when the door is removed.

Speed adjustable while Engine is running. Requires less care than any other Engine known, and uses less oil. **NO OIL IS LOST.** Engine easily understood. No complications Inside. Constructed to stand hard work. The Patent "Safety" Governors are Extremely Sensitive. They are mounted on the Crank Shaft and require no belt to drive them, and are everlasting.

Letter from Superintending Engineer of Sixteen Steamers with these Engines on board, says:—"*All the Engines are working very satisfactorily.*"

CHANDLER CROMPTON COMBINED COMPOUND PLANT.

For SHIP LIGHTING and TRAIN LIGHTING, as supplied to the Cape Government Railways and many Steamers.

WHEATLEY KIRK, PRICE and GOULTY

(ESTABLISHED 1850).

ELECTRICAL AUCTIONEERS, VALUERS, AND ARBITRATORS.

49, QUEEN VICTORIA STREET, LONDON, E.C.

And Albert Square, MANCHESTER.

SALES BY AUCTION, &c.

SALE of ELECTRIC MOTOR TRAM CARS, DYNAMOS, SHAFTING, FURNITURE, and Other Effects.

WHEATLEY KIRK, PRICE AND GOULTY are instructed to SELL BY PUBLIC AUCTION, Early in MARCH, At the Electric Tram Car Station, known as Plashet Hall Works, Romford-road, Forest Gate, London, E., The ENTIRE CONTENTS of the above Premises.

The Sale will include SIX ELECTRIC MOTOR CARS, specially built for 4ft. 8½in gauge, together with a variety of Plant, Furniture, and Effects.

Catalogues may be had shortly from the Auctioneers, WHEATLEY KIRK, PRICE AND GOULTY, 49, Queen Victoria-street, London, E.C.; and Albert-square, Manchester. Telegrams, "Indices, London."

SALE OF HIGH-CLASS NEW MACHINE TOOLS, ENGINES, DYNAMOS, and ELECTRICAL FITTINGS.

WHEATLEY KIRK, PRICE AND GOULTY are instructed to include in their Sale at the Electric Tram Car Station, Forest Gate, London, E., as above, about 20 New High-class Lathes, also numerous Electroliers, several thousand Switches, Lamp Holders, Instruments, Dynamos, Motors, new Shaping Machine, new High-speed Vertical Engines, about 1,000 dozens Yellow Metal Gas Fittings, consisting of Cocks of various kinds, Sockets, Pendant Bodies, Unions, Swivels, Bracket Backs, Ceiling Plates, &c.; 600 dozens Bib and Stop Cocks, Plumbers Brass Work and Gun-metal Steam Fittings.

Catalogues may be had shortly from the Auctioneers, WHEATLEY KIRK, PRICE and GOULTY, 49, Queen Victoria-street, London, E.C.; and Albert-square, Manchester. Telegrams, "Indices, London."

STOCK and PLANT of an ELECTRICAL ENGINEER.

MESSRS. F. J. BISLEY AND SONS WILL SELL BY AUCTION, At their SALE ROOMS, 80, UNION ROAD, ROTHERHITHE, S.E., On THURSDAY, MARCH 2nd, at Twelve for One o'clock precisely,

Electric Light Fittings, about 300 2 to 8-cell finished and unfinished Batteries, large quantity of Porous Pots and Plates, Carbon Plates, Zinc Rods, Electric Lamp Fittings, Copper Wire, Switches, Bell Pushes, &c., carboy of Sulphuric Acid, 2 4ft. Lathes on iron stands, a 2ft. 9in. Victoria Lathe by Selig Sonnenthall and Co., 3 4in. Jaw Vices, Zinc Cutter, Screw Die Press, Stocks and Dies, Tools and Miscellaneous Effects.

ON VIEW day prior.

Catalogues of the Auctioneers, Cheshire House, Rotherhithe, and 63, King William-street, City, E.C.

COUNTY BOROUGH OF HUDDERSFIELD.

ELECTRIC SWITCHES, &c.

The CORPORATION OF HUDDERSFIELD are prepared to receive SAMPLES and TENDERS for the supply of MAIN SWITCHES and MAIN FUSES for Controlling the Supply of Electrical Energy to Consumers' premises.

Full particulars may be obtained on application to the Borough Electrical Engineer.

Samples and sealed Tenders to be forwarded to Mr. A. B. MOUNTAIN, Borough Electrical Engineer, Gasworks-street, Huddersfield, not later than WEDNESDAY, the 15th March, 1893, and the tenders must be endorsed "Main Switches, &c."

By Order, H. BARBER, Town Clerk.

Town Hall, Huddersfield, 15th February, 1893.

SITUATIONS VACANT AND WANTED, &c.

COUNTY BOROUGH OF BOLTON.

The BOLTON CORPORATION are prepared to APPOINT an ELECTRICAL ENGINEER to have charge of the construction of the works of electric installation intended to be carried out for the Borough and to have the management of such works when completed. He will be required to devote the whole of his time to the duties of the appointment.

Salary to commence with £200 per annum.

Applications, stating age and experience, together with testimonials, to be delivered to the undersigned on or before the 22nd February, 1893.

By order, R. G. HINNELL, Town Clerk.

Town Hall, Bolton, 1st February, 1893.

A LEADING private FIRM of Electric Light Contractors want a competent DRAUGHTSMAN; principal qualifications, being competent to make neat Drawings for private installations, and the various details in connection therewith.—Apply, DRAUGHTSMAN, *Electrician* Office, Salisbury-court, Fleet-street, E.C.

ELECTRICAL ENGINEER.—WANTED, for a high-tension Electrical Supply Station, as soon as possible, but not later than May 1st, a SUPERINTENDENT ENGINEER, to take entire charge of the station and of the electrical and mechanical plant. Applicants are requested to send for a form giving particulars.—Address, MANAGING DIRECTOR, Bath Electric Light Works.

VACANCY for WORKING FOREMAN in a high-class London electrical and scientific instrument shop; must be reliable, experienced, intelligent and energetic. A suitable man will receive considerate treatment and opportunity of advancement.—Full particulars (in confidence) to 1593, *Electrician* Office, Salisbury-court, Fleet-street, E.C.

WANTED, a superior YOUTH, about 20, who can do repairs to electric light and fill up spare time in office.—1172, *Electrician* Office, Salisbury-court, Fleet-street, E.C.

ELECTRICAL ENGINEER, with eight years' practical experience with leading firm, seeks RESPONSIBLE POSITION in Central Station or Electrical Business, London or Provinces.—1166, *Electrician* Office, Salisbury-court, Fleet-street, London, E.C.

ELECTRICIAN (age 20) desires RE-ENGAGEMENT, Meter Department or Central Station, four years' experience high and low tension. Good references.—"W. S.," 135, High-street, Margate.

ELECTRICAL ENGINEER (21) seeks ENGAGEMENT. Thoroughly experienced in Continuous Current Arc, Incandescent lighting, Accumulator and Power Plants. Good references —"W. E. T.," 73, Excelsior-street, Waun, Llwyd, Mon.

MECHANICAL ENGINEER, with good knowledge of electricity, desires SITUATION in Works, or Central Station.—"J. D.," 485, Shields-road, Glasgow.

SCIENTIFIC and ELECTRICAL INSTRUMENT MAKER, accurate workman, requires SITUATION in Workshop or Laboratory. Good references.—"M.," 37, Gold-street, Stepney, E.

TO ELECTRICAL and other ENGINEERS.—WANTED to place a premiumed PUPIL, working with a good go-ahead firm.—Letters to "GUARDIAN," care of J. W. Vickers, 5, Nicholas-lane, E.C.

A FIRM of ELECTRICAL ENGINEERS is open to negotiate with Manufacturers for SHOW and REPRESENTATION in West End of London. Light Fittings, Telephones, Bells, &c.—Box 855, Sell's Advertising Offices, London.

MANUFACTURING.—Electric Light Engineer, with extensive plant at work in W.C. District, will entertain PROPOSALS to take up the MANUFACTURE of SPECIALITIES or other goods on very reasonable terms.—No. 1,012, *Electrician* Office, Salisbury-court, Fleet-street, E.C.

MAGNETOS and RECEIVERS, &c., WANTED 100 per month.—JAMSON, 1067, Pollockshaws-road, Glasgow.

FOR DISPOSAL.—A COMPLETE PLANT, comprising a 7 h.-p. Crossley Gas Engine and a Dynamo for 140 lights, with Belt and Switch-board. Also a Set of E.P.S. Accumulators for 75 lights. Can be seen working in the city of London.—Address, "A. L.," *Electrician* Office, Salisbury-court, Fleet-st., E.C.

LAING, WHARTON and DOWN have a number of EDISON and COLLAR LAMP HOLDERS, which are not latest type, and which they would sell at a great reduction.—Can be seen at their Works, Haunch of Venison-yard, Brook-street, W.

MESSRS. DEBENHAM, TEWSON, FARMER, and BRIDGEWATER have a large selection of SHOWROOMS, OFFICES, WAREHOUSES, and FACTORIES suitable for ELECTRICAL ENGINEERS. Their Monthly List is now ready, and may be obtained at their Offices, 80, CHEAPSIDE, E.C., or will be forwarded free by post

THE ELECTRICIAN:

A WEEKLY ILLUSTRATED JOURNAL OF

ELECTRICAL ENGINEERING, INDUSTRY AND SCIENCE.

No. 770.—Vol. XXX. FRIDAY, FEBRUARY 17, 1893. PRICE FOURPENCE.
Annual Subscription (U. K.), 19/6

NOTES.

The electricity supply business is evidently settling down to the prosaic but healthy function of dividend paying. Following on the declaration of a 7¼ per cent. dividend by the St. James' and Pall Mall Company come similar announcements of a more modest character from the Kensington and Knightsbridge Company and from the Westminster and Electricity Supply Corporations. The Kensington and Knightsbridge Company is able to give its ordinary shareholders a 4 per cent. return for their money, the Westminster Corporation gives them ½ per cent. less, and the Electricity Supply Corporation leads the way with a 5 per cent. dividend. The alternately inflated and vanishing dividends of many electrical manufacturing concerns have consisted of oscillations, obeying no doubt some law of financial inertia, and proportional, perhaps, to the square root of the tightness of the market divided by the capital. These oscillations have died away with a logarithmic decrement, and the moderate returns of electricity supply companies are decidedly welcome, the more so since, so far as we can judge without that full knowledge of all the facts to which managing directors can alone lay claim, these dividends are the *bona fide* outcome of hard work.

With the very full figures supplied by the Board of Trade form of accounts, there is a great temptation to indulge in all manner of comparisons and statistical juggling, with the result that the deductions made are almost as wearisome as the actual accounts themselves. We shall therefore only call attention to a few leading facts in these accounts and compare one or two items in each set.

Taking the Kensington–Knightsbridge and Westminster accounts together, as relating to areas of much the same character, the following comparative table may be helpful to a general idea of their relative positions. Both concerns it may be observed have a modest depreciation or renewal fund.

—	Kensington and Knightsbridge.	Westminster.
Paid-up Capital	£154,000	£370,000
Net area of District supplied	·67 sq. mile	1·9 sq. miles
Capital density per sq. mile	£230,000	£194,736
Lamps connected, Dec. 31,1892	47,441	98,686
Increase on 1891	23%	57%
Lamp density per sq. mile	70,807	51,940
Dividend	4%	3½%

The areas covered by the St. James' and Pall Mall Company and the Electricity Supply Corporation are alike in character and similar in size, so that a bald comparative table is even less likely to do injustice to one side or the other than in the previous instance. It should be added that the St. James' and Pall Mall Company have set aside something for depreciation and to redemption of capital, in addition to maintaining their plant in good repair, whilst the Electricity Supply Corporation has not as yet done so.

—	St. James' and Pall Mall.	Electricity Supply Corporation.
Paid-up capital	£200,000	£200,900
Net area	0·24 sq. mile	0·18 sq. mile
Capital density per square mile	£833,333	£1,116,111
Lamps connected Dec. 31, 1892	48,000	29,000
Increase on 1891	24·4%	—
Lamp density per square mile	200,000	161,111
Dividend	7¼%	5%

At the centenary celebration of the Newcastle Literary and Philosophical Society last week Lord Armstrong showed the interesting "dust figures" produced by Leyden jar discharges on dust-strewn glass plates. These figures are of great intricacy and beauty, but until theory can be made to explain them, or until they can throw some light upon theory, it is difficult to give them a place in electrical science. Knowledge for knowledge' sake is, as Lord Armstrong says, a worthy object of pursuit, but unless it is co-ordinated knowledge it is not scientific knowledge.

Another experiment, less popular, perhaps, but more interesting because less complicated, was the relative motion of cotton thread and of the water with which it was wetted, under electrical influence. Two glasses were filled to the brim with pure water, and were connected by a cotton thread. A powerful induction coil discharge was passed, and the thread was rapidly drawn over, while water not only passed in the opposite direction, but when the whole of the thread had been deposited in one glass, there remained "for a few seconds a rope of water suspended between the lips of the two glasses." A modification of this experiment was performed with a cotton wick in a glass vessel submerged in water, and two concentric currents of water were shown, the inner one moving in what may be called the direction of the current, and carrying the cotton with it, but remaining distinctly visible when the cotton was removed, and a surrounding sheath of water moving against the current.

Hosted by Google

A DEFECT of the Baconian system is that it tends to divide and subdivide the phenomena of nature into categories which are daily increasing in number; every fresh experiment or group of experiments is found to present new classes or species of results. It becomes necessary at times to generalise, not so much for the higher purpose of arriving at some underlying principle by which they may all be explained, as to find some rational head under which they may be conveniently grouped. Electrolysis remained for many years the only known process of molecular transference. It was and must still be considered as a chemical process, and the migrating components have been called "ions." A number of cases of transfer are now known in which no chemical decomposition takes place; none, at all events, need be postulated. Such are the phenomena which take place in gases as described by Mr. BALY in his Paper before the Physical Society last week; in the oils mentioned by Prof. S. P. THOMPSON in the discussion following this Paper; in the tannin in electrical tanning; in the cataphoric transfer of drugs; with FARADAY'S silk threads; with Prof. RAMSAY'S indigo; and even with the cotton wicks in Lord ARMSTRONG'S experiment. There are no ions here, and where such components are found they may, perhaps, be regarded as the result of so strong a tendency to transference that chemical decomposition is effected. It would be well if attention were directed to the phenomena of electrical transference as a whole, of which electrolysis is but a special case.

THE vigorous attack by Mr. SAM MAVOR on the usual method of wiring, and his forcible, though we do not say convincing, plea for concentric conductors, is worth half-a-dozen colourless articles on the subject. The reader knows, at all events, that he is listening to a warm partisan, and weighing the merits of each argument in turn, he will not be so confused as if he had attempted to digest a mixture of conflicting opinions. When Mr. MAVOR offered us the article which will be found in another column, we asked him to include in it some details of experience with wiring that had stood at least two years, but he informed us that it was impossible to do so, since "the beauty of concentric wiring is that its use is absolutely void of incident," and added that he had examples (he called them installations, by the bye) which had been running for four, five, and six years. We do not wish to criticise his arguments, but would point out that, as far as disturbance of compasses on board ship is concerned, concentric wiring is in precisely the same case as single wiring.

CONCENTRIC wiring labours under two disadvantages. It is hedged in on all sides by patents; none of these can be called master-patents, but it seems hardly worth while to go to the trouble of avoiding patented devices. Another difficulty is that its use either entails the earthing of one side, a practice on which not only opinions but authorities differ, or, owing to the necessarily large diameter of the outer conductor, expensive external insulation. If insulating tubes such as those mentioned in our Trade Notes of last week are to be relied on for this purpose, they might meet this difficulty, but on this point we have no information.

THE endeavour to find a material to replace platinum in the construction of glow lamps is not likely to cease because the price of that metal has fallen, although the search will not be so important as once appeared. Ordinary iron wire appears to be used in the new Westinghouse lamp, and a long length imbedded in the glass appears to be relied upon. An alloy of iron, nickel, and antimony platinised, has, according to *La Lumière Electrique*, been proposed by Dr. LANGHANS, and is said to have nearly the same co-efficient of expansion as glass. It is not at all clear why this should be the case. Brass and bronze alloys have a co-efficient of expansion nearly proportional to their constituents, while in the case of tin and zinc the co-efficient is higher than that of either of the components. The co-efficient of expansion of antimony between freezing and boiling point is 0·00113, of nickel 0·00125, and of wrought iron from 0·00112 to 0·00116. Cast-iron promises best, with a coefficient of 0·001; but all these are a long way above glass, which is about 0 00089. Platinum has a coefficient of 0·000863, and, as is well known, it is not difficult to make a special kind of glass which will approach much more nearly to platinum in its expansion than ordinary qualities. The coefficient of porcelain is considerably lower than that of glass. A German journal says that an alloy of "melted copper, added to 95 per cent. melted tin," holds excellently to clean glass, having nearly the same coefficient of expansion. Its melting point is said to be 360°C. Unless the coefficient of this alloy differs in some remarkable manner from those of its components, the result might be expected to be rather worse than ordinary copper, which has a coefficient of 0·0016. The determination of the coefficient of various alloys is a rather tedious operation, and, like many other properties of mixed metals, has received very little attention.

FOR fire-office inspectors and electricity supply company officials the Syndicat Professionnel des Industries Électriques have, with characteristic logic and precision, substituted a Bureau de Contrôle des Installations Électriques, with M. R. V. PICOU at its head. This Bureau is to undertake the testing and periodic inspection of wiring and the collection of electrical data of all sorts. Although an offshoot of the Syndicat Professionnel, the operations of the Bureau are to be entirely independent of it. The question of ways and means appears to be satisfactorily settled for the present by subsidies, and a sufficient income is expected to be derived in future from fees for work done. The institution of this Bureau de Contrôle is another instance that our French neighbours are not to be deterred from taking a certain course merely because it happens to be logical.

Southport.—The Local Government Board have sanctioned the borrowing of £28,000 for electric lighting.

Ipswich.—The Board of Trade have given notice that they have revoked the Ipswich Borough Electric Lighting Order.

Cable Interruptions—

	Interrupted.
Cayenne-Vizeu	Sept 24, 1892

The Chicago-St. Louis Electric Railway.—The contract for the construction of this railway has, it is said, been let, and the line is to be completed one year from the beginning of work.

Hosted by Google

"Electrical Railways."—Under this title a Paper by Dr. Edward Hopkinson was read before the Institution of Civil Engineers on Tuesday last. The Paper was practically confined to a general description of the City and South London Railway. An interesting discussion may be expected.

Royal Society.—The following Paper was down for reading yesterday, by E. H. Griffiths:—"The Value of the Mechanical Equivalent of Heat, deduced from some Experiments performed with the view of establishing the Relation between the Electrical and Mechanical Units."

The Lighting of the Embankment.—The Parliamentary Committee of the County Council have asked for an additional £5,000 to complete the sum required for lighting the Albert Embankment, Westminster, and Waterloo Bridges, and the Victoria Embankment, by electricity. The total cost is now set down at £15,000.

London Electric Supply Corporation.—The London Electric Supply Corporation announce that from April 1st next their standard charge for electrical energy will be 6d. per Board of Trade Unit. All customers will also be entitled to the benefit of a sliding scale extending from the standard rate of 5d. per unit, based on their consumption of energy.

Hanley.—The Local Government Board have given their consent to the borrowing of the money necessary for the carrying out of the electric light project of the Town Council. A Provisional Order was obtained by the Council in June, 1891. On September 6th last the Council accepted the tender of the Brush Electric Engineering Company of £15,760.

The Endowment of Research.—Mr. Ludwig Mond, who has contributed so munificently to the expenses of the special researches on oxygen which Prof. Dewar is carrying out in the laboratory of the Royal Institution, has, it is stated, given a donation of £2,000 to the Royal Society in aid of the further compilation of their catalogue of scientific papers.

The Brown Non-Synchronous Motor.—We have received, too late for our correspondence columns, a letter from MM. Hutin and Leblanc, in which they state that the motor described by Mr. Brown in our issue of Jan. 27 was invented by them in 1890. They refer to a complete description of the theory in *La Lumière Electrique* of May 30, 1890. On referring to this publication (Vol. 40, p. 418) we find a highly mathematical article, containing a plan and an elevation of a 15-kilowatt motor, which had been built at the factory of the Société l'Eclairage Electrique.

Institution of Electrical Engineers.—At the last meeting of this Institution the President announced that the Council had received from Sir David Salomons a very handsome donation in the shape of £500 New South Wales Three and a-Half per Cent. Stock, to be added to the Salomons Scholarship Fund; and at the same time £20 for the Benevolent Fund.

The Göbel Glow Lamp.—In the *Electrical Engineer* of New York, of January 25th, under the title of "The Carbon Filament Lamp of 1859: the Story of an Overlooked Invention," Mr. Franklin Leonard Pope gives an interesting little sketch of the life and doings of Heinrich Göbel, the alleged anticipator of Edison, to whom our New York correspondent referred in his letter last week.

Lambeth Vestry.—The Electric Lighting Committee of this Vestry submitted a long report at the last meeting, recommending the Vestry to take steps to put in force the provisions of the Lambeth Electric Lighting Order, asking that the Committee might be authorised to negotiate for a site for a central station, and recommending the Vestry to obtain powers to borrow £75,000 to be solely supplied for the purposes of electric lighting. This recommendation was adopted.

Bath.—At the last meeting of the Town Council a report was presented from the Lighting Committee, which said that the inspector reported that the experiments to detect faults were not successful, and that the Company proposed to send out two men at proper intervals each night to ascertain and report as to lamps gone out. It was resolved that the penalty of 5s. per extinguished lamp should be enforced against the Company from and after February 1st, and that notice should be given to the Company.

Soldering Aluminium.—It is announced that the problem of soldering aluminium has been solved by Prof. J. W. Richards, of the Metallurgical Department, Lehigh University, U.S.A. Very soon after the birth of the aluminium industry the Société d'Encouragement in France voted a prize of £1,000 for its successful solution. De Mourey, of Paris, was awarded the prize. His solders were only moderately successful. The sole agent for the Richards solders in this country is Mr. W Archibald Briggs, East Dock-street, Dundee.

Bradford.—At the last meeting of the Town Council, Alderman Priestman, in moving the adoption of the minutes of the Gas and Electricity Supply Committee, said that he had just got the half-yearly statement of his two departments. The gas section showed a profit for the half-year of £2,274, and in the electricity department the profit for the half-year had been £1,089. He also stated that the total amount expended on capital account in connection with the electric supply was £48,568. They at present owed to the bank £4,308, and on loans £47,291, and they had paid to sinking fund, out of revenue, £3,198.

The Plymouth Telephone Service.—At the annual meeting of the Plymouth Mercantile Association last Monday the report of the Association contained the following passage:—

> The members of the Association will recollect that towards the close of the preceding year many complaints of the inefficiency of the telephone service were brought to the notice of the Committee. These were tabulated, and a general consensus of opinion was obtained, and the information gathered handed over to a Committee of the subscribers to the local exchange. The Association is pleased to have been instrumental in assisting so important a section of its members, and to know that considerable improvement has resulted. The telephone service is still far from perfect, and it is improbable that it can be as efficient as the subscribers would desire and are entitled to until a double metallic circuit is provided.

The Boudreaux Dynamo Brush.—In *L'Electricien* for January 28th, M. Em. Dieudonné sings the praises of a dynamo brush devised by a M. Boudreaux, an electrotyper. The material of which the brushes are composed is an alloy of copper, zinc, and silicium. This alloy is highly malleable, and is beaten out into thin strips two to three hundredths of a millimetre (0·8 to 1·2 mils.) thick, and is then made up into suitably shaped brushes, presenting a foliated texture, the mass of the brushes being far more homogeneous than that of wire or copper-strip brushes. M. Dieudonné claims that this type of brush keeps the commutator smooth, and that the wear is inappreciable.

The Vienna-Buda Pesth Electric Railway Scheme.—Lecturing a few days ago in Vienna on the projected electric railway between that city and Buda Pesth, Mr. J. Kareis, of the Vienna Electrotechnical Society, stated that the cost of constructing the line would amount to two and a-half times that of an ordinary railway. The present traffic between the two cities was 200,000 passengers per annum, and even if all these were diverted to the electric railway Mr. Kareis was of opinion that the receipts would not provide anything for depreciation or any interest on the capital outlay. If, however, the suggested speed were reduced to 93 miles an hour, the cost of construction would be diminished.

Sunspots and Magnetic Disturbances.—In a note in the *Comptes Rendus* of the 6th inst., Prof. G. E. Hale, of Chicago, refers to the commonly held belief that there is a close connection between terrestrial magnetic disturbances and the passage of spots or of faculæ across the centre of the solar disc. Observations taken by the spectroheliograph at Kenwood Observatory since February, 1892, however, tend to upset this theory. Spots and faculæ are shown to be so numerous that the chances are about nine to one that at any instant some are crossing the solar meridian. Hence, it is not surprising, says Prof. Hale, that at the moment of any given magnetic disturbance on the earth there should be a group of faculæ or spots either on the central meridian or at the edge of the sun.

The London County Council and Technical Education.—The debate on the proposals of the London County Council's Special Committee on Technical Education was resumed on Wednesday. The proposal that the Technical Education Board should be appointed for a term of three years, and be composed of 35 members, of whom 20 should be members of the

Hosted by Google

County Council, was discussed. It was decided that the Board should be elected annually, instead of triennially as originally proposed. The representation of the School Board was reduced from five to three, and that of the London Trades' Council was raised from one to three. An amendment, giving a seat to the London Chamber of Commerce was rejected. The Committee's next recommendation that an annual report and financial statement should be presented by the Board to the Council was adopted without discussion. The next recommendation, to the effect that "every district of London ought to be adequately provided with technical education of every grade, rising from the school to the workshop and the university, and appropriate to the chief occupation of its inhabitants," was discussed at length before adoption. The last recommendation that one-third of the total amount estimated to be receivable under the Local Taxation Act 1890 should be appropriated to technical education, was carried after an unsuccessful attempt to get one-half substituted for one-third.

A Recently-Discovered Anomaly in the Secular Variation of the Magnetic Needle.—In the *Comptes Rendus* of January 9th, M. Léon Descroix states that in 1882 he published a comparative table of the observed and calculated values of the magnetic declination for 150 years. The interpolation formula which he deduced represented the facts at that time with a fair degree of accuracy, and it was considered justifiable to extrapolate the probable value of the magnetic declination for a quarter of a century ahead. A memoir of M. Faelheggen, of the Gottingen Observatory, in which a completely different mathematical method was employed, showed that the deviation of the needle at Paris between 1880 to 1890 would be 81′, a similar figure to that arrived at by M. Descroix. As a matter of fact, it was only 65′. M. Descroix then states that in order to obtain further verification of this interesting anomaly, attributable, perhaps, to the exceptional physical disturbances of recent years, he again went over his data. Moreover, he consulted the publications of the observatories of Paris, St. Maur, Bordeaux, London, Copenhagen, Palermo, and Coimbra, and the net result went to show that there was an appreciable retardation of the excursion of the magnetic needle. M. Descroix then asks whether this is only a temporary variation, or whether the predicted slowing-down of the excursion has definitely commenced. It may be stated that it is thought that something of the kind happened in 1760.

Telegraphing Mr. Gladstone's Speech.—In view of the telegraphic despatch of reports of Mr. Gladstone's speech on Monday evening last, great preparations were made by the postal telegraph officials. Extra Wheatstones and "punchers" were fitted up at the central telegraph office, wires were added to all the principal circuits of the kingdom, and several towns not normally in direct connection with London were put through. The main East Coast line of the Postal Telegraph Department carrying twenty important wires, was subjected to considerable damage near Hatfield on Monday morning. Some workmen engaged in cutting trees allowed a heavy branch to fall right across the wires, smashing all of them at that point, and breaking six wires and four wires in the two adjacent spans. The accident occurred between twelve and one o'clock. The sectional engineer, Mr. Parkinson, was at Welwyn at the time, and received intimation of the disaster at 1 p.m. He drove at once to Hatfield, a distance of 10 miles, taking with him a line man and some necessary stores. They arrived on the scene of the breakdown at 1:50, got three of the wires through by 3:15, and the whole 20 were again working by 4:10. This was sharp work, and enabled the line to carry its share of the very heavy traffic caused that evening by the introduction of the Home Rule Bill. Three-quarters of a million words were sent out on Monday evening from the Central Telegraph Office. This is a very high figure, but it has been exceeded on two or three occasions.

Obituary.—The death is announced of Dr. Norvin Green, President of the Western Union Telegraph Company. Dr. Norvin Green was born in 1818. He studied medicine at the University of Louisville, where he graduated in 1840 with honours. He then established a successful medical practice, and became the physician of the Western Military Academy at Drennon Springs, Kentucky. He was elected for several terms to the Kentucky Legislature. He ultimately became one of the lessees of the United Morse and People's Telegraph line between Louisville and New Orleans. Thenceforth Dr. Green identified himself with the history of the telegraph, and in 1866, when the American United States and Western Union lines were consolidated, Dr. Green was chosen Vice-President, and, with the exception of about three years, retained that office until, in 1878, he succeeded Mr. William Orton as President of the Western Union Telegraph Company, which position he held until his death. His early life was characteristic of the extreme West, and made him an example of the best type of the American youth. In his sixteenth year he procured a flat boat, stocked it with groceries and other ordinary supplies, and floated down the Mississippi River. His chief customers were lumbermen, who at certain seasons entered the low river lands to make rafts ready to be floated out on high water. The venture was a successful one, and laid the foundation of his business experience. Dr. Green was a man of many remarkable qualities. His disposition was gentle, kind, and charitable, and his loss is sincerely mourned.

The Proposed Cable to New Caledonia.—The French Government have submitted to the Chamber a Bill to subsidise the laying of a cable before September 22nd next between Queensland and New Caledonia on the ground of the inconvenience and delay in the existing postal service between Australia and New Caledonia. They propose guaranteeing £8,000 yearly for thirty years on condition that the cable, &c., must be laid by a French ship, worked by a French staff, and controlled by a French Directorate in Paris, such control not to be transferred without the special consent of the French Government. The Government of Queensland's undertaking to give this foreign venture exclusive landing rights for thirty years forms part of the arrangement, but no provision or promise of assistance appears in the Bill for any extension of the cable across the Pacific, which, according to the Queensland Government Postal Report 1891, was to form the principal feature of the project. It is difficult to understand the action of Queensland in this matter, because that colony has always been foremost in advocating the establishment of submarine communication across the Pacific to the United States or Canada *entirely under British control.* The scheme is consequently adversely criticised in this country as preventing the laying in the future of a British cable from Queensland, and encouraging foreign enterprise. It is to be noted that the late Mr. Sandford Fleming, as well as other eminent Canadians and several Australian Statesmen have in the past objected to any Pacific cable being laid which would be in any way in foreign hands.

Water-Tube Boilers.—At a recent meeting of the Junior Engineering Society a Paper was read by Mr. Harry Fraser on "Water-tube Steam Boilers." The author stated that so much trouble had arisen from fluctuations of pressure in water-tube boilers that their adoption had been much retarded. To overcome this defect the diameter of the water and steam receivers had been largely increased. It was necessary that ample means should be provided for downward circulation. Straight tubes should be used in preference to bent, and they should be arranged in such a way that any one tube could be replaced without interference with the others. A water space should receive the first vertical heat from the fire, and should have an adequate supply of the coldest water of the boiler, and an efficient means of escape for the steam direct to the receiver. The good result of fitting a water-cased furnace was shown graphically by a diagram prepared from figures obtained from trials. The usual angle of inclination of the tubes was 20deg. with the horizontal. The methods of fixing tube ends adopted by De Naeyer, Yarrow, De Temple, Debarbe, Montorpet, and Fraser were described and illustrated. Of water-tube boilers for land use, particulars and results of working were given of the Babcock and Wilcox, De Naeyer, Mills, and the author's. Of those for torpedo boats the De Temple, Thornycroft, and Yarrow were described. Two water-tube boilers adapted for marine use had been designed by the writer for the s.s. "Grappler," on which there was at present a boiler of the ordinary marine kind, so that comparisons of their performances would be readily drawn, and would doubtless prove of considerable interest and value.

THE DIFFUSION OF LIGHT.

BY W. E. SUMPNER, D.SC.

(*Concluded from page 412.*)

A convenient way of ascertaining the reflecting power of a diffusing surface is to compare it directly with that of blotting paper. If, instead of the Methven standard at L (*see* Fig. 1), a sheet of blotting paper, of area A′, be erected at the end of the bench opposite the screen O R, the reflecting power of the surface of O R is given by the formula

$$r = 0{\cdot}82 \frac{x^4}{y^4} \frac{A'}{A}.$$

This method has the advantage that it is independent of any fluctuation which may occur in the light K.

There is one remarkable peculiarity of a diffusive reflector which is well worthy of notice. An ordinary mirror reflects light almost equally well for all directions of incidence, and where any difference exists it is found that rays which make a large angle with the normal to the surface suffer less absorption than those which are nearly perpendicular to it. With a diffusive reflector, on the other hand, the light is mostly sent off in the normal direction, and however the light may be incident upon the surface, it is diffused.

This can easily be shown by placing immediately behind a glow lamp first a piece of common mirror and secondly a sheet of white paper. In the former case the candle power of the lamp is found to be nearly doubled, but in the latter case it is far more than doubled. In the former case, however, the candle power is doubled in all directions on one side of the mirror, while in the latter the statement is only true for directions in the neighbourhood of the normal to the paper reflector. A plane white reflector is therefore more efficient than a plane mirror when it is desired to increase the light in one direction only, for it reflects about twice as much light as the mirror in different directions in accordance with a perfectly fixed law of proportions. A common mirror reflecting 80 per cent. of the light incident upon it from a lamp, produces an image of the lamp whose candle power is 0·8 times that of the lamp, and this candle power is nearly the same for all directions. But a piece of white paper illuminated by a lamp sends off most of its rays in the normal direction, and, although its reflecting power may not exceed 80 per cent., it is quite possible for a white reflector to more than double the candle power of the lamp for a particular direction.

Measurement of Absorption.

The absorbing power of some of the preceding substances were determined by measuring the candle-power of the light from a glow-lamp, first when this was uncovered, and afterwards when it was surrounded with a cylinder of the paper under test. The cylinders were short, being just longer than the height of the lamp, and were closed at top and bottom with caps of the same paper, so that the lamp was completely enveloped by the paper tested. The ratio of the diminution of candle-power to the original candle-power gave the *apparent* absorption of the paper. If the candle-power in some particular case was found to diminish 30 per cent., it would have been erroneous to conclude that the envelope absorbed as much as 30 per cent. of the light incident upon it, or that 70 per cent. was transmitted. If the reflecting, absorbing, and transmitting powers of a material be respectively denoted by r, a, and t, there must exist between these quantities the relation

$$r + a + t = 1.$$

Also if Q be the quantity of light given out per second by the light source within the envelope, the quantity of light incident per second upon the surface of the envelope will, owing to internal reflexion, be increased to Q′, where

$$Q'(1 - r) = Q;$$

the quantity of light absorbed and transmitted will respectively be

$$a\,Q' \text{ and } t\,Q',$$

and the ratios these quantities bear to Q will similarly be

$$a/(1 - r) \text{ and } t/(1 - r);$$

the sum, of course, being unity.

If the light source can be assumed to radiate equally in all directions, the ratio of its candle-power, after putting on the envelope, to the original candle-power will not be t, but $t/(1 - r)$. The influence of internal reflection is to increase *both* the absorption and the transmission, and unless it is taken into account large errors may be made in estimating the coefficients. A very simple way of showing the effect of internal reflection consists in surrounding a glow lamp with a white paper cylinder, open at the top, and adjusting a photometer screen till the illumination caused by it is balanced against that of some standard source of light. If now a piece of white paper be placed on the top of the cylinder, so as to shut in the vertical rays of the lamp, the candle-power in the horizontal direction will be found to increase considerably. In some of the tests, in order to avoid error caused by non-uniform radiation of the lamp, this was first surrounded with an envelope of tracing-cloth, or blotting-paper, and the combination used as the light source. If k_0 be its candle-power in this condition, and if k_1 be the observed candle-power after completely surrounding it with an envelope of the substance to be tested, the apparent absorption of this material is

$$\frac{k_0 - k_1}{k_0},$$

and the true absorption coefficient a is given by

$$a = (1 - r)\frac{k_0 - k_1}{k_0},$$

where r is the previously found reflexion co-efficient. (*See* Table I., page 381).

When an inner envelope is used to produce a light which radiates equally well in all directions, it is necessary for the outer envelope to be large compared with it, since otherwise the formula for the increase of illumination due to internal reflexion cannot be applied.

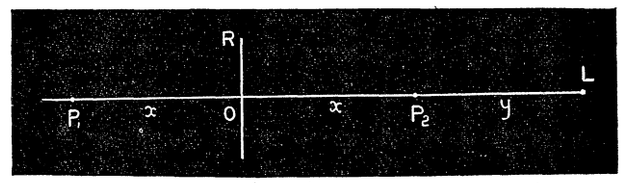

FIG. 3.

The following table gives the values of the absorbing coefficients expressed as percentages, for the four substances at the head of Table I. :—

Table IV.

——	Apparent absorption.	Absorption coefficient.
White blotting-paper	77 per cent.	13·8 per cent.
White cartridge-paper	61 ,,	12·2 ,,
Tracing-cloth	23 ,,	15·0 ,,
Tracing-paper	9 ,,	7·0 ,,

Three large glass globes, made for arc-lamps, were also tested. As the reflective powers of the globes could not easily be found, only the apparent absorption was measured. One globe was of opal glass (almost transparent), and the ratio of apparent absorption was 15 per cent. A second globe was of ground glass and absorbed 42 per cent. The remaining one was of opal glass, too opaque to allow any bright object placed within it to be distinguished. This absorbed 39 per cent.

Measurements of Transmitting Power.

The amount of light transmitted through the surfaces above mentioned was measured in a very similar manner to that in which their reflective powers were determined; the only difference being that the glow-lamp at P_1 (*see* Fig. 1, page 412) was moved to the opposite side of the surface as in Fig. 3.

O R represents the screen of paper, pinned on a wooden frame, and placed perpendicular to the optical bench P_1 L. The glow-lamp was at P_1, the photometer at P_2, and the Methven standard at L. In all the tests the distances O P_1, O P_2, were arranged to be equal, and balance was obtained by moving L

Hosted by Google

along the bench. It can then be shown that the formula already given for reflection holds equally well for transmission, and with the same notation as before we have

$$t = \frac{L}{K}\frac{x^2}{y^2}\left\{\frac{\pi x^2}{A} + 1{\cdot}75\right\},$$

t being the coefficient of transmission, assuming that all the light transmitted is diffused. It was found, however, that all the four substances tested were more or less transparent, so that while a portion t_1 of the incident light was scattered in accordance with the law of diffusion, another part t_2 was transmitted without change of direction. This must obviously be the case with substances like thin opal glass, which are sufficiently transparent to enable the eye to clearly distinguish objects through them, and it seems only natural for it to be true of translucent surfaces, which, when placed between the eye and the light, appear brightest just where the surface is cut by the straight line joining the light to the eye. The result, however, appears true for nearly all surfaces which transmit light at all, and even thick blotting paper transmits nearly 3 per cent. of the incident light without any change of direction.

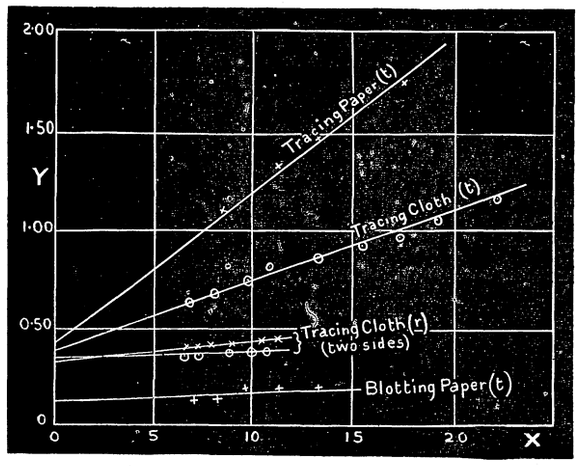

FIG. 2.—Value of $X = \frac{\pi x^2}{A} + 1{\cdot}75$.

Value of $Y = \frac{L}{K}\frac{x^2}{y^2}\left\{\frac{\pi x^2}{A} + 1{\cdot}75\right\}$.

In order to separate the effects of diffused and regular transmission, it became necessary, as before, to make measurements for several values of the distance x. The coefficients t_1 and t_2 are connected by the equation

$$\frac{L}{K}\frac{x^2}{y^2}\left\{\frac{\pi x^2}{A} + 1{\cdot}75\right\} = t_1 + \frac{t_2}{4}\left\{\frac{\pi x^2}{A} + 1{\cdot}75\right\},$$

and, as before, by plotting a curve connecting the observed values of Y and X, where

$$Y = \frac{L}{K}\frac{x^2}{y^2}X,$$

and

$$X = \frac{\pi x^2}{A} + 1{\cdot}75,$$

the values of t_1 and t_2 were found. The numbers given in Tables V. and VI. indicate the nature of the results obtained, and the general agreement of the experimental numbers with those calculated from the formulæ. The observations are plotted in Fig. 2, and the results are summarised in Table VII.

In Table VIII. the reflecting, absorbing, and transmitting coefficients have been collected, and the sum of these quantities is given in the last column. This sum should be unity, or 100 per cent. The excess above the theoretical value is probably due to a slight difference between the actual law of diffusion and that which is generally assumed to hold. The formulæ used above have been obtained on the assumption that a diffusing surface scatters its light in different directions with an intensity proportional to the cosine of the angle which the direction considered makes with the normal to the surface. A very slight divergence from this law would be amply sufficient to account for the small discrepancies shown in the last column of Table VIII.

Table V.—*Transmitting Power of Blotting-Paper.*

ON THE DETERMINATION OF THE INSULATION RESISTANCE AND OF FAULTS IN ELECTRICAL PLANTS DURING THE WORKING.

BY DR. O. FROELICH.

(*Continued from page 414.*)

Method 3. (Fig. 3. Two-galvanometer method.)—This method is more suitable for observing the insulation continuously in the engine room, for example, but it will also serve

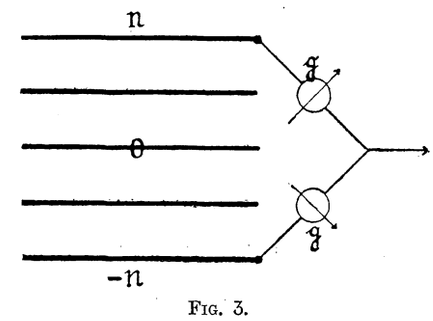

FIG. 3.

to determine the insulation. If one galvanometer is inserted between the point n and earth and, at the same time, a second one between $-n$ and earth, the deflections of the two instruments are in different directions, but equal when the faults on both sides of the middle point are symmetrically distributed ($h = 0$); the algebraic difference of the deflections gives the difference of potential of the points n and $-n$. When a fault developes on one side of the circuit, the deflection of the instrument, which is nearer to the fault, diminishes, and the deflection of the other instrument increases in the same portion;

Hosted by Google

the (absolute) difference in the deflections is proportional to h or, generally speaking, to the difference of insulation on either side of the middle point. If we take off one galvanometer and read the deflection of the other one, and *vice versa*, we can calculate the resistance of the insulation by the simultaneous and the separate deflections.

When both instruments are simultaneously inserted, the potential of the middle point is

$$P'_0 = (h - n/g + ng)/(K + 2/g) = (h)/(K + 2/g).$$

whence the sum of the potentials at n and $-n$:—

$$P'_n + P'_{-n} = 2\,P'_0 = (2\,h)/(K + 2/g).$$

If only one instrument is inserted at n, the potential at n is

$$P''_n = (h - n/g)/(K + 1/g) + n\,\delta.$$

If the same operation is executed at $-n$, the potential at $-n$ is

$$P''_n = (h + n/g)/(K + 1/g) - n\,\delta, \text{ whence}$$

$$P''_n + P''_{-n} = (2\,h)/(K + 1/g). \quad . \quad . \quad . \quad (3b)$$

By the equations 3*a* and 3*b* we find

$$K = -1/g + 1/g[P'_n + P'_{-n}]/[P''_n + P''_{-n} - (P'_n + P'_{-n})] \quad (3c)$$

As in methods 1, 2, 3, the expressions for K and F contain only quotients of the potentials, the galvanometers need not be calibrated in volts; but it is nevertheless useful to do so, in order to know the absolute potentials.

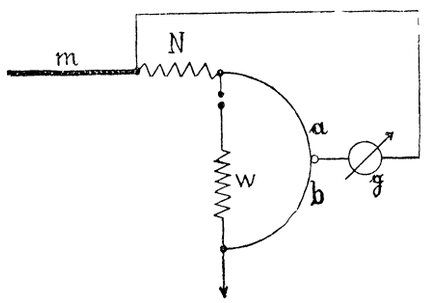

Fig. 4.

Method 4. (Fig. 4. Bridge method.)—Here we consider the whole circuit as one point connected to earth by the resistance F, and insert this resistance as fourth side branch of an ordinary bridge, the known resistance N serving as third side branch. The contact moving on the branches a and b is placed so that by opening and closing the diagonal branch w the galvanometer g shows the same current. Then we have

$$F = N\,b/a \quad . \quad . \quad . \quad . \quad . \quad . \quad (4)$$

Single or Resultant Fault.

If there exists only one fault, or if the other faults are so small that the resultant fault coincides nearly with the heavy

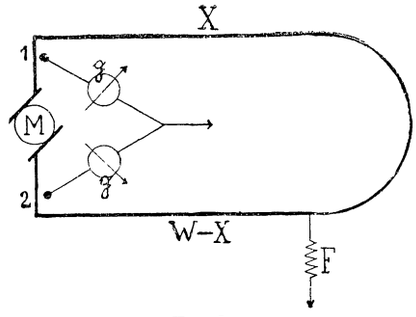

Fig. 5.

one, we can determine, during the working of the plant, not only the resistance, but also the position of the resultant fault.

Method 5. (Fig. 5. One Galvanometer at Two Points.)—Herr Frisch has determined the resistance of the insulation by inserting a galvanometer between two points, one after the other, of the circuit and earth; and by the same process we can also determine the position of the resultant fault. Let us denote by: I the main current, X the resistance between the pole 1 and the fault, W the external resistance between the poles 1 and 2, g the resistance of the galvanometer, F of the fault, i_1, i_2 the currents (taken positive towards earth) measured by the galvanometer, when it is inserted between 1 and earth and between 2 and earth respectively. Then we have

$$i_1 = I\,(X)/(g + F),\ i_2 = -I\,(W - X)/(g + F),$$

whence

$$X/W = i_1/i_1 - i_2 = 1 + i_2/(i_1 - i_2) \quad . \quad . \quad . \quad (5)$$

This very simple method is best combined with the two galvanometer method No. 3. If in the use of this last method we observe a considerable difference of the two simultaneous deflections, we take off one instrument and read the other, and *vice versa*; so the currents and i_1, i_2 are obtained, and from these the locus of the fault. As there is no difference of the deflections taken simultaneously when the fault is at the middle point or the insulation is symmetrical to the middle point, it is useful to read from time to time the single deflections also; by that we make sure that there is no resultant fault at the middle point.

Method 6. (Figs. 6 and 6A. Bridge method.)—The wire of the bridge or the ends of the bobbins forming the two variable branches of the bridge are connected to the poles of the dynamo, the galvanometer is inserted between the moveable contact and earth, the resistance W with a contact breaker is also placed between the poles; the contact is placed so that by

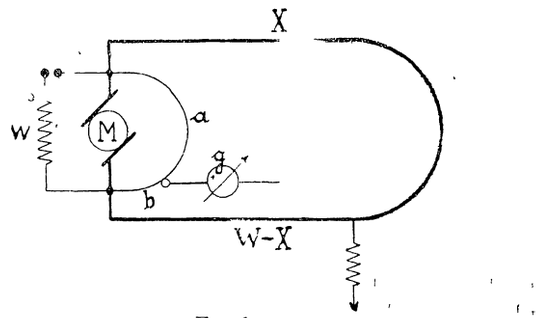

Fig. 6.

opening and closing w the deflection of the galvanometer does not change. Then we have

$$X/W = a/(a + l) \quad . \quad . \quad . \quad . \quad . \quad (6)$$

The same method can be applied to find the place of a fault in a machine during the working of the machine (*see* Fig. 6*a*). The connections are the same, only the external circuit is best removed; but it can also remain in connection, if its insulation is good. If the fault is in the shunt n of the machine, the place found by the test is the real place of the fault; if the fault is in the armature the place found by the test will be in the middle between the poles, in consequence of the rotation.

If in a central station a heavy fault appears, the main conductor, which contains the fault, can be determined by methods 4 or 5.

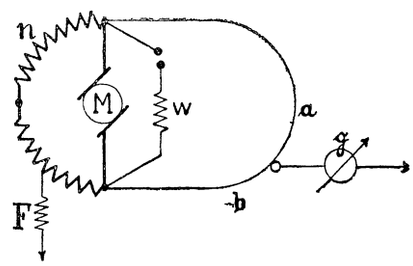

Fig. 6A.

Several Faults at Known Places; Faults on the Main Conductors of a Central Station.

Method 7. (Fig. 7.)—The problem of how to find the positions and resistances of several faults, which exist together on a circuit, has not been solved up to the present; but it is possible to solve it, when the places are known beforehand. If a central station contain only arc and incandescent lamps faults can only possibly exist on the main conductors and feeding

Hosted by Google

cables, which are here considered as one. Let us develop this case, and show how to find, during the working of the plant, the resistance of the fault of each main conductor. These tests can be carried out every day, and serve to show continuously the state of the insulation of each main conductor, and enable us to get warning of faults, which are increasing slowly, previous to becoming serious defects. This is possible when the insulation of the whole circuit is known and bridge tests are taken between two neighbouring main conductors (*see* Fig. 7). The number of the faults is equal to the number of main conductors and to the number of the bridge tests; but one of these tests is always a consequence of the other ones, so that the bridge tests do not suffice, and the knowledge of the insulation must be made to help us.

To find the formula, by which the quotient a/b, found in the balancing the bridge, is expressed by the resistances f or the conductivities k of the faults of the main conductors, the theory of the bridge (*see* Diagram C) had to be developed; the Wheatstone bridge is only a special case of this system. I shall only give the results of this theory for the systems of five, three, and two conductors. The connections for the bridge test in a system of three wires are shown in Fig. 7.

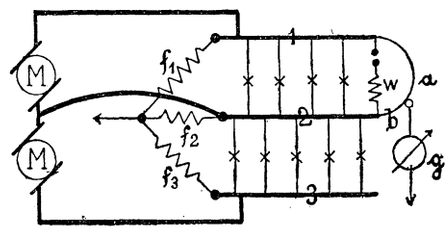

FIG. 7.

System of Five Conductors.—In this p, q, r, s, t are the resistances denoted in Diagram C, by f_1, f_2, f_3, f_4, f_5, the resistances of the faults; let us put $k_1 = 1/f_1$, $k_2 = 1/f_2$, &c., $K = \Sigma 1/f = \Sigma k$; m_{51} may be the value of a/b, if, as in Diagram C, the wire of the bridge is inserted between 5 and 1; m_{12} the value of a/b, if the insertion takes place between 1 and 2, &c.

We form the expressions:

$$\text{(7a.)}\quad \begin{aligned} \mu_{51} &= (1-m_{51})/(1+m_{51}),\\ \mu_{12} &= (1-m_{12})/(1+m_{12}),\\ \mu_{23} &= (1-m_{23})/(1+m_{23}),\\ \mu_{34} &= (1-m_{34})/(1+m_{34}),\\ \mu_{45} &= (1-m_{45})/(1+m_{45}); \end{aligned}$$

then the following relation exists between the five values μ:

$$\text{(7b.)}\quad \begin{aligned} 0 = \mu_{51}\, t\,(p+q+r+s) + \mu_{12}\, p\,(q+r+s+t)\\ + \mu_{23}\, q\,(r+s+t+p) + \mu_{34}\, r\,(s+t+p+q)\\ + \mu_{45}\, s\,(t+p+q+r). \end{aligned}$$

If we calculate k_1, k_2, &c., from the known values μ and p, q, &c., and suppose that the resistances p, q, r, s, t of the lamps and machines are small in proportion to those of the faults f_1, f_2, &c., we arrive at last at the following formulæ:—

$$\text{(7c.)}\quad \begin{aligned} \frac{k_1}{K} &= \frac{t+p+\mu_{51}\,(p+q+r+s)-\mu_{12}\,(q+r+s+t)}{2\,(p+q+r+s+t)}\\ \frac{k_2}{K} &= \frac{p+q+\mu_{12}\,(q+r+s-t)-\mu_{23}\,(r+s+t+p)}{2\,(p+q+r+s+t)}\\ \frac{k_3}{K} &= \frac{q+r+\mu_{23}\,(r+s+t+p)-\mu_{34}\,(s+t+p+q)}{2\,(p+q+r+s+t)}\\ \frac{k_4}{K} &= \frac{r+s+\mu_{34}\,(s+t+p+q)-\mu_{45}\,(t+p+q+r)}{2\,(p+q+r+s+t)}\\ \frac{k_5}{K} &= \frac{s+t+\mu_{45}\,(t+p+q+r)-\mu_{51}\,(p+q+r+s)}{2\,(p+q+r+s+t)} \end{aligned}$$

In practice we can suppose that the resistance l, inserted between two neighbouring main conductors, is the same everywhere, because, if the numbers of the lamps are not equal, the equalisation is obtained by insertion of resistances, accumulators or dynamos. Consequently we can put $p=q=r=s=l$ and $t=m$, the resistance of the machines, and we obtain:—

$$\text{(7d.)}\quad \begin{aligned} \frac{k_1}{K} &= \frac{l+m+4\,l\mu_{51}-(3l+m)\,\mu_{12}}{2\,(4\,l+m)}\\ \frac{k_2}{K} &= \frac{2\,l+(3\,l+m)\,\mu_{12}-(3\,l+m)\,\mu_{23}}{2\,(4\,l+m)}\\ \frac{k_3}{K} &= \frac{2\,l+(3\,l+m)\,\mu_{23}-(3\,l+m)\,\mu_{34}}{2\,(4\,l+m)}\\ \frac{k_4}{K} &= \frac{2\,l+(3\,l+m)\,\mu_{34}-(3\,l+m)\,\mu_{45}}{2\,(4\,l+m)}\\ \frac{k_5}{K} &= \frac{l+m+(3\,l+m)\,\mu_{45}-4\,l\,\mu_{51}}{2\,(4\,l+m)} \end{aligned}$$

m is known and remains constant; l can be calculated by the main current and the difference of potential between two neighbouring conductors; thus we can, when the conductivity K of the insulation is known, and the values μ are calculated from the bridge tests, determine the conductivity k, or the resistance f, of the fault of every main conductor.

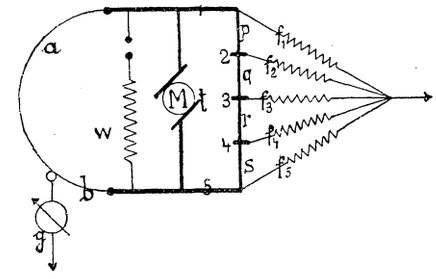

Diagram C.

System of Three Conductors.—If we denote again by t the resistance of the machine, by p, q those of the lamps, the formulæ are as follows:—

$$\text{(7e.)}\quad \begin{aligned} \frac{k_1}{K} &= \frac{t+p+\mu_{31}\,(p+q)-\mu_{12}\,(q+t)}{2\,(p+q+t)}\\ \frac{k_2}{K} &= \frac{p+q+\mu_{12}\,(q+t)-\mu_{23}\,(t+p)}{2\,(p+q+t)}\\ \frac{k_3}{K} &= \frac{p+t+\mu_{23}\,(t+p)-\mu_{31}\,(p+q)}{2\,(p+q+t)}. \end{aligned}$$

If we again put $t=m$, $p=q=l$, we have—

$$\text{(7f.)}\quad \begin{aligned} \frac{k_1}{K} &= \frac{l+m+2\,l\,\mu_{31}-(l+m)\,\mu_{12}}{2\,(2\,l+m)}\\ \frac{k_2}{K} &= \frac{2\,l+(l+m)\,\mu_{12}-(l+m)\mu_{23}}{2\,(2\,l+m)}\\ \frac{k_3}{K} &= \frac{l+m+(l+m)\,\mu_{23}-2\,l\,\mu_{31}}{2\,(2\,l+m)}. \end{aligned}$$

(To be continued.)

CONCENTRIC WIRING.

BY SAM MAVOR, M.I.E.E.

Engineers who are engaged in or associated with electric light wiring constantly have impressed upon them the extreme unsatisfactoryness, from a mechanical point of view, of the methods usually employed. The lavish use—amounting to a craze—of crockery is the most prominent and jarring feature, from a mechanical standpoint, of existing practice. It is used for switches, cut-outs, ceiling roses, pulleys, counter-weights, lampholders, shades, shade-carriers, &c. This is due chiefly to the Fire Office inspectors, and is a splendid tribute to their persistent influence. The attitude which they have rightly adopted in insisting upon a high standard of insulation combined with fireproof parts has led to the almost universal introduction of this unmechanical and, in appearance, clumsy and cheap and nasty material. The use of porcelain is not

Hosted by Google

here condemned, but its misuse. Another weak point in present practice is the very large number of parts involved. Take, for example, an ordinary ceiling rose with cut-out, such as is commonly used. In this piece of apparatus there are a porcelain base, three small brass plates, six small brass screws, and a porcelain cover—11 parts, inclusive of the base. If a cord grip is used additional parts are added. In a mill with 500 lights there are thus, in the ceiling roses alone, 5,500 separate and individual parts. When switches, sub-main cut-outs, &c., are reckoned, the total number of parts is appalling. As Mr. Preece long ago pointed out, every binding screw and every unsoldered contact is a weak point which will probably cause trouble sooner or later. Where, as on board ship and in many factories, vibration and a damp atmosphere are encountered the probability becomes a certainty. The necessity of providing wood casing for the mechanical protection of the conductors is another objection to existing practice. It is impossible to lay wood casing throughout a completed building without excessive damage to floors and joists or interference with the decorations. Owing to the expense involved in making good work of the wood casing and the usual absence of a clerk of works to supervise, this portion of the work is rarely equal to the other wood work of a building. The wood casing where laid on the surface in many of the best buildings in London is a disgrace, and would not for a moment have been tolerated either in arrangement or workmanship, by an architect or his clerk of works. Further, wood casing harbours moisture, does not protect from rats, and in mansions frequently costs 50 per cent. of the total cost of wiring. Electric light wiring carried out with double conductors laid in wood casing *cannot*, even with the best materials and workmanship, be made absolutely and infallibly fireproof.

How are all these objections, mechanical, electrical and insurance, to be surmounted? The adoption of concentric wiring consistently and well carried out with uninsulated return makes a clean sweep of them—wipes them right out. The outer conductor in a concentric system must have conductivity at least equal to the centre wire, and must form a complete and continuous metallic envelope or sheathing around it. The continuity, mechanical and electrical, of this metallic envelope must be uninterrupted throughout the system. Where fuses, cut-outs or switches are used these must be in the centre wire, and must be entirely enclosed in metallic boxes or covers. All such boxes or covers must form part of the outer conductor. The outer conductor should not only be left uninsulated throughout its length, but should be positively "earthed" at the main switchboard or distributing centres. It has been objected that by adopting concentric wiring with earthed return the risk of breakdown is doubled, owing to one conductor being already earthed. This is a mistake when applied to concentric wiring. The outer conductor being at earth potential no shock or spark or risk can be experienced from it. There is therefore only one vulnerable conductor, and this being enclosed throughout its entire length by a metallic sheathing is well protected against injury. The liability to breakdown is therefore very much less with concentric than with double wiring. The risk attending a breakdown of insulation in double wiring with wood casing due to dampness or other injury is great, and has resulted more than once within the writer's experience in the casing being set on fire by the leakage—fuses notwithstanding. With concentric wiring there is no such risk. A leak in a concentric conductor cannot endure. In the event of the insulation between the inner and outer conductor being damaged the fault immediately developes into a short circuit and burns out the fuse. The spark passes from the centre conductor to the inner side of the metallic sheathing, and being entirely *within* the sheathing cannot communicate fire to its surroundings. Concentric wiring when consistently carried out is absolutely fireproof.

Concentric wiring may also be readily made waterproof. The conductors are waterproofed by a sheathing of lead laid under or over the outer conductor. Waterproof joints are easily made between the lead sheathing and the cast brass switch or fuse boxes. The simplicity with which this may be done can only be appreciated by those who have laboriously endeavoured to make double wiring waterproof. A system of double wiring recently illustrated and described in a contemporary was devised to comply with the latest regulations issued by the Home Office in regard to the electric lighting of explosives factories. The essential requirements in such a case are that the wiring shall be fireproof, dust proof and waterproof. The methods employed in the effort to meet these requirements with double wiring were laudable attempts to make the best of a bad job. Had the designer known with what simplicity and safety these and other stringent regulations have been met by concentric wiring he would have been spared the perverted exercise of his ingenuity.

With regard to shipwork—it is well known to those experienced in this department that wiring in order to be durable under the conditions met with at sea must be waterproof. The difficulty of rendering double wiring waterproof, coupled with the keenness with which this class of work is competed for has led to the matter being shirked by contractors. Notwithstanding the extensive and constant repairs required to the wiring of steamships, and the frequently reported cases of fires on board ship due to defective wiring the old methods go merrily along. The British Admiralty four years ago realized the necessity of waterproof wiring, and at that time began to specify lead-covered conductors, but this, although a vast improvement on the old methods, was only a step in the right direction. For while specifying waterproof conductors and joints throughout, the old pattern switches, cut-outs, fittings, &c., were retained, with the result that faults constantly developed in them and at their bases. The necessity of having these appliances made waterproof has for years been strongly urged upon the Admiralty by several contractors and impressed upon them by their own experience. The result was the adoption about six months ago of waterproof patterns of switches, cut-outs, distributing boxes, fittings, &c. And in taking this further step the difficulty indicated above—of making a system of double wiring waterproof—has been encountered in full force. The new Admiralty patterns are the result of much care and deliberation. Waterproof they may be, but clumsy and expensive they certainly are. Their appearance is strong evidence of the difficulty of designing waterproof fittings for double wiring, where the two sides of the circuit must be insulated from each other and from the containing boxes. The simplicity and compactness of concentric fittings complying with the necessary requirements are a striking contrast. Now that the Admiralty have fully realised the necessity of waterproof wiring their next step may be to adopt in concentric wiring the readiest means of attaining the desired result. There is prejudice to be overcome on the part of the navigating officers, who have an idea that disturbances to the compasses arise from the use of concentric wiring. It is certainly possible to so arrange concentric wiring that the compasses shall be disturbed; but when the proper precautions, now well understood, are taken, there is no chance of such disturbance. A very large number of concentric wired ships are now at sea, and trouble to the compasses from this cause is unheard of. The danger may, indeed, be greater from double wiring. A fault may develop in one conductor, connecting it with the ship's ironwork in the neighbourhood of a compass. A disturbance might thus be caused to the compass by the current in the sound conductor—all the more dangerous from the fancied security which double wiring gives. For petroleum vessels also, where fire risk is great, concentric wiring affords the readiest, most effective, and least expensive means of rendering the wiring fireproof.

The standard of insulation attained in concentric wiring is uniformly very much higher than is usual in double wiring. From eight to twelve times the requirements of the Phœnix Fire Office is the normal result. And with conductors, joints, &c., in a continuously hermetically sealed metallic sheathing, and switches and fuses in cast brass waterproof boxes, the insulation is unaffected by moist atmosphere or surroundings. Herein lies a very important point in favour of concentric wiring, namely, that it excludes the arch enemy of good insulation, moisture, and gives permanency to the high standard of insulation.

Much more might be said on behalf of concentric wiring if space permitted, but only one other important feature will

Hosted by Google

here be noted, namely, that it lends itself so admirably to mechanical treatment. That concentric wiring, having all the advantages herein claimed, has not hitherto received a larger measure of attention from electrical engineers is matter for surprise. There is a natural reluctance of contractors, who have been at much pains to standardise their patterns, to organise their system of working, and train their staffs in their methods, to change their system.

Such a change, unless carried out gradually, would inevitably lead to temporary friction and a good deal of worry. But the possible friction attending the initiation of an improvement would be a poor argument against its introduction. The prejudice which has existed against concentric wiring has almost disappeared. The groundlessness of this prejudice is shown by the absence of valid objections to counterbalance the unquestionable advantages. A little experience of concentric wiring always converts its most strenuous opponent into its most enthusiastic advocate.

NON-SYNCHRONOUS MOTOR FOR ORDINARY ALTERNATE CURRENTS.

BY E. ARNOLD.

In No. 767, January 27th, you publish a communication from Mr. C. E. L. Brown on the above subject. For those who have followed the literature or have been engaged in the development of alternate current motors it is of interest to know the way in which Mr. Brown uses the methods of Elihu Thomson and Nikola Tesla in the construction of his alternate current motors. It is evident that the development of a good alternate current motor is of first importance for the distribution of power, and that the experience gained in the construction of multi-phase current motors is of the greatest value in the construction of motors for ordinary alternate currents.

The Oerlikon Works are well known as constructors of multi-phase motors, and recently a table of results was published by Mr. E. Kolben. They have also for some time been constructing single-phase motors, and early in 1892 the first non-synchronous motor was built. It was not a complete success, but by repeated experiments and careful study they succeeded in constructing a series of motors for ordinary alternate currents as standard types of the following sizes : $\frac{1}{8}$, $\frac{1}{4}$, $\frac{3}{4}$, $1\frac{1}{2}$, 2, 3, $4\frac{1}{2}$, 6, and 9-H.P. These motors have neither commutator, brushes, nor contact rings. They run non-synchronously, and their efficiency is very nearly equal to that of triple-circuit motors.

In Chur (Switzerland), where the Oerlikon Works have fitted up an alternate current central station, there are three of these motors running—namely, a 2-H.P. motor driving the printing machinery of the *Neue Brindner Zeitung ;* a $4\frac{1}{2}$-H.P. motor on the premises of Mr. Schmid, butcher ; and a 9-H.P. motor used for starting the 100-H.P. synchronous alternate current motor in Messrs. Lendi and Parli's mill.

The inducing winding of these motors is either "Gramme" or "drum" wound, and is embedded in grooves in the laminated iron ; the induced or rotating part carries a winding which is short circuited in certain groups or with a complete ring at each end.

For starting, the rotating part must be given a certain speed : this can be done in various ways—viz., for the smaller sizes a pull on the belt is sufficient, the motor will then get up the proper speed itself and take the load. To start with a load, the method given by Nikola Tesla may be adopted, that is to say, the method described by Mr. Brown in Figs. Nos. 7, 8, and 9. Another method, pointed out at the same time by Dr. Behn and the writer, is used by the Oerlikon Works, namely, the inducing winding is divided into several sections, and is connected with the segments of a current reverser (built up like a collector) fixed on the switchboard ; by means of a hand wheel with double brush-contacts sliding on the segments of the current reverser a rotating field is produced and the motor will start, the motion of the brushes on the current reverser can then be stopped in any position.

A third method suitable for large motors has been devised by the writer ; it is quite similar to that shown by Mr. Brown in Figs. 12 and 13. The following extract from the specification for Provisional Protection, sent to the English and American Patent Offices last year, will show the full similarity.

Extract from specification (pages 7 and 8) :—

"The armature is assumed to be a Gramme ring. As in a continuous current machine the separate bobbins are connected with the segments of a collector, on which slide two brushes. On starting the motor the primary current is supplied not only to the field, but also to the armature. The alternate current motor now works with correct position of the brushes as a series motor for continuous current. The maximum current in the armature always coincides with the maximum field. The motor will consequently start under favourable conditions, and with considerable torque. The resistance included in the circuit allows the strength of current and torque to be regulated. As soon as the armature approaches the synchronous motion, which takes place in a short time, the collector segments are short circuited with each other. For this purpose serves an insulated ring capable of sliding on the shaft, and which is slid by means of a lever against the collector plates. The current now passes directly from one brush to the other. The sparking on the collector is entirely obviated, and the armature works as a short circuit armature. By the use of a short circuiting device the brushes can be entirely removed from the collector after starting the motor. By means of a centrifugal governor the pulling in and out of gear of the short circuiting ring can be effected automatically, &c.'

PHYSICAL SOCIETY.

At the ordinary meeting, which followed the annual general meeting on February 10th, Mr. E. C. C. BALY made a communication on

"Separation and Striation of Rarefied Gases under the Influence of the Electric Discharge."

On examining with a spectroscope a vacuum tube containing a small quantity of hydrogen, the author noticed that the hydrogen lines were strongly visible in the negative glow, but could not be seen in the body of the tube. This observation was confirmed by examining other tubes, and seemed to point to a separation of gases in the tube. From subsequent experiments it also appeared that the striæ were due to this separation. By using a double tube containing a mixture of carbon dioxide and hydrogen, whose parts were connected by a narrow, neck which could be sealed and the part detached, the gases were fractionated by the discharge. After sealing off, the spectra of the two parts were examined ; the one that had formed the positive pole showed only a trace of hydrogen, whilst the other showed it brilliantly. Other mixtures gave similar results, and the separation was found not to depend on the relative molecular weights of the gases. A very close connection between separation and striæ was noticed, the two phenomena always occurring together. If the author's views were correct a pure vapour or gas should not striate. Experiments tended to confirm this. The author therefore concludes, first, that when an electric current is passed through a rarefied mixture of two gases, one is separated from the other and appears in the negative glow ; second, that striæ are caused by the separation of the two gases, and do not act in a single pure gas or vapour.

Mr. BLAKESLEY read a communication from Dr. W. Crookes relating to Mr. Baly's Paper, and pointing out that in his Presidential Address to the Institution of Electrical Engineers in January, 1891, he had given reason for believing that stratification was due to the gas not being homogeneous.

Prof. RAMSAY said no proof had been given that electrolysis occurred in such tubes, and it was an open question whether molecules could convey electricity as ions do. So far as was seen, no ions existed in vacuum tubes. Possibly the stratification resulted from collisions of molecules giving higher temperatures at some parts of the tube ; but this was doubtful.

Mr. ENRIGHT thought the analogy with electrolysis was not quite clear, for in a mixture of simple gases the elements were not combined chemically, and electrolysis involved the splitting up of chemical compounds.

Prof. S. P. THOMPSON hoped the author would continue his important work, and clear up the doubtful points in vacuum tube phenomena. Some difficulty existed in classifying the separation of the gases, with electrolysis, for in the latter the effects were only visible at the electrodes, and not in intermediate portions of the substance. The question whether vacuum tube discharges were strictly analogous might be tried by fractionating through a series of tubes. Prof. Schuster had considered the analogies in his Bakerian Lecture, and published some important results, some of which tended to show that wandering ions existed in vacuum tubes through which discharges were being passed. Referring to Prof. Ramsay's remarks about molecules not carrying electricity, he said that electric winds were phenomena which pointed to the opposite conclusion. Similar convective action also occurred in turpentine and other insulating liquids. He wished to know whether the author had tried if a low voltage (say 100 volts) applied for a long time to a vacuum tube would produce separation of the contained gases. Porret's phenomenon of electric osmose seemed to have

Hosted by Google

some bearing on the subject, as also Faraday's observations on the movements of scraps of silk in turpentine, and showing that in non-conducting liquids there were phenomena somewhat analogous to electrolysis.

Prof. RAMSAY said that if indigo were put in a poor conductor, such as distilled water, and the mixture subjected to electrolysis, all the blue colour became concentrated about one electrode, whilst if arsenic sulphide be similarly treated the colour went to the other pole. On mixing the two solutions all coagulates and goes down. He could give no explanation of these remarkable effects.

In his reply, Mr. BALY said that he had tried the experiment with complicated tubes as suggested by Prof. Thompson, but the result was not conclusive.

THE MAGNETIC PROPERTIES OF SUBSTANCES AT VARIOUS TEMPERATURES.*

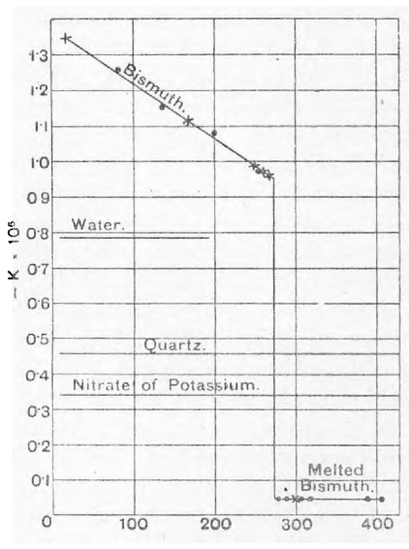
BY P. CURIE.

The author investigated the magnetic properties at different temperatures of a large number of diamagnetic bodies. None of these substances exhibited any sensible remanent magnetism, and the coefficient of magnetisation was constant at each temperature for fields varying from 50 to 1,350 C.G.S. units. The results are given in the table below, in which K = coeff. of sp. magnetisation per gramme :—

Substance.	Temp. C	$10^6 \times K$
Bismuth (solid)	20°	−1·350
„ „	273°	−0·957
„ (liquid)	273°−405°	−0·038
Antimony (electrolytically deposited)	20°	−0·680
„ (solid)	535°	−0·460
„ (after heating to 535°)	20°	−0·940
Phosphorus (ordinary liquid or solid)	19°−71°	−0·920
„ (red)	20°−275°	−0·740
Water	15°−189°	−0·790
Rock salt	16°−455°	−0·573
Chloride of potassium	18°−465°	−0·550
Sulphate of potassium	17°−460°	−0·430
Nitrate of potassium (solid or liquid)	18°−420°	−0·329
Quartz (parallel or normal to axis)	18°−430°	−0·441
Sulphur (octahedric, prismatic, flowers, solid or liquid)	15°−225°	−0·510
Selenium (solid or liquid)	20°−415°	−0·320*
Tellurium	20°−305°	−0·311
Bromium	20°	−0·410*
Iodine (solid or liquid)	18°−164°	−0·380*
Palladium	14°	+5·150
Oxygen	20°	+115·000

* Samples not as pure as could be wished.

It will be observed that the coefficients of sulphur, nitrate of potassium, iodine, and selenium are unaffected by change of state in these bodies. Antimony and bismuth, on the other hand, have decreasing coefficients with rising temperatures. These results,

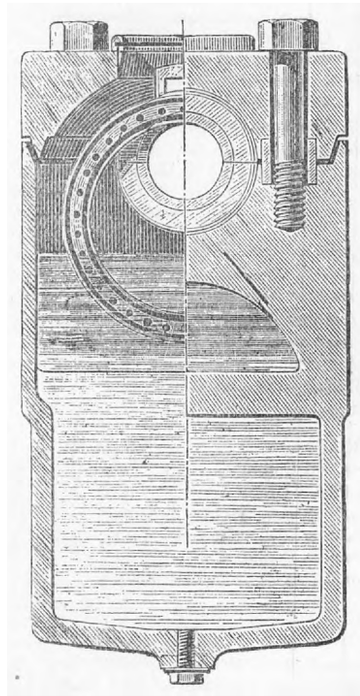


obtained with diamagnetic bodies, are interesting when compared with those obtained for magnetic bodies, for which, generally speaking, the coefficient diminishes as the temperature rises, the diminution following a hyperbolic curve. The law followed by bismuth (*see* curve) is something very different to the hyperbolic law.

* Abstract from the *Comptes Rendus*, January 23rd, Vol. CXVI., No. 4.

THE HENRION SYSTEM OF OILING BEARINGS.*

A modification of the well-known system of oiling bearings by means of a ring dipping into an oil bath has been introduced by M. Fabius Henrion, of Nancy. The objection to the plain ring is that it throws off the lubricant by centrifugal force in all directions which results in waste and other inconveniences. As shown in the annexed cut M. Henrion provides the ring with a number



Henrion Bearing Lubricator. Sectional Elevation.

of cavities which enable it to bring the oil up to the top whence it is spread over the bearing by a number of grooves. By means of a piece of glass let in at the top the condition of the bearing can be inspected.

MEETINGS OF SCIENTIFIC SOCIETIES, &c.

(TO-DAY) FRIDAY, February 17th.

INSTITUTION OF ELECTRICAL ENGINEERS.

8 p.m. Students' Meeting. Paper to be read: "Cost of Private Installations," by W. L. Bayley.

MONDAY, February 20th.

CHEMICAL SOCIETY.

8 p.m. Extra Meeting. Kopp Memorial Lecture by Prof. T. E. Thorpe, F.R.S.

SOCIETY OF ARTS.

8 p.m. Cantor Lecture (4): "The Practical Measurement of Alternating Electric Currents," by Dr. J. A. Fleming, F.R.S.

TUESDAY, February 21st.

INSTITUTION OF CIVIL ENGINEERS.

8 p.m. Ordinary Meeting. Paper to be further discussed: "Electrical Railways," by Dr. Edward Hopkinson, M.A., and monthly reception by the President and Council.

WEDNESDAY, February 22nd.

OLD STUDENTS' ASSOCIATION.

7.30 p.m. Meeting at Finsbury Technical College. Paper to be read and discussed: "The Series Method of Teaching Foreign Languages, and its Application to the Technical Professions," by Howard Swan.

SOCIETY OF ARTS.

8 p.m. Ordinary Meeting. Paper to be read: "Old Age Pensions," by T. Mackay.

THURSDAY, February 23rd.

INSTITUTION OF ELECTRICAL ENGINEERS.

8 p.m. Ordinary General Meeting. Paper to be read: "Note on testing Alternators," by W. M. Mordey.

FRIDAY, February 24th.

PHYSICAL SOCIETY.

5 p.m. Papers to be read: (1) "A handy Focometer," by Prof. J. D. Everett; (2) "Plane and Spherical Sound Waves," by Dr. C. V. Burton; (3) "Motion of a Perforated Solid in a Fluid," by G. H. Bryan, M.A.

DR. FLEMING ON TRANSFORMERS.

Dr. FLEMING'S Paper on "Experimental Researches on Alternate Current Transformers" forms an important addition to the literature of the subject, and the statistical information in which it abounds will be of considerable value for both practical and for theoretical purposes. It will be referred to by transformer makers, who may learn what their transformers must do if they are to compete with those of the leading makers; by engineers who may discover reliable data for designing supply systems; and, we hope also, by theoretical men who are so fond of writing about the performance of imaginary combinations of iron and coils of wire. Besides this, the Paper contains much useful information about methods of electrical measurement, and not only bare descriptions of such methods, such as are to be found in books, but careful considerations of the errors that are likely to arise, and of the corrections that should be made or precautions that must be observed. Important as the Paper is, there has been a sad waste of time over the discussion. The Paper was read on November 24, 1892, and the next communication to the Institution of Electrical Engineers will not be made until the 23rd of this month. Christmas and the Presidential Address have intervened it is true, but the additional information brought out during the debate bears no proportion to the large part of the session which has been spent upon it.

Hosted by Google

The conclusions arrived at in Dr. FLEMING's Paper are not numerous, and, compared with the final conclusion brought out in his reply, are not of great importance. He has disproved, we hope for the last time, the theory that the losses in transformers fall off at heavy loads; we have opposed this idea from the very first, not on account of a private revelation of the laws of nature, but, firstly, on the strength of a common sense intuition, and, secondly, owing to a total absence of reasons to support the supposed experimental evidence. The same conclusion was buried in a British Association Paper by Prof. AYRTON and Dr. SUMPNER last year, together with a comparison of the losses of closed and open-circuit transformers. Dr. FLEMING has confirmed these tests, and his results are more general since his experiments were made on many types of transformers; and as his method of testing is more intelligible, his work appeals to a wider audience. The fact that the core losses in open-circuit transformers are nearly four times as much as theory indicates is a mystery which has yet to be solved. If a mere reduction of mechanical pressure on the iron wires is all that is needed, or even if, as a further precaution, the secondary conductor is stranded, will these transformers then justify the promises made in regard to them in 1889 at Newcastle? Neither Dr. FLEMING nor anyone else has pointed out any fallacy in the calculations on which these open-circuit transformers have been designed, and there is at present reason to suppose that faults of construction, or, perhaps, of the quality of the iron, have given rise to the abnormal losses. It must be remembered that when "Hedgehog" transformers came out with a flourish of trumpets, their calculated performances were compared with the actual results of the transformers of those days. Dr. FLEMING's Paper shows what advances have been made since then, but if the original calculations were not fallacious, it may be supposed that open-circuit transformers, when properly made, will have some *raison d'être* other than mere cheapness, since the "Hedgehog" transformers tested by Dr. FLEMING gave at full load as high an efficiency as that of the average closed-circuit transformers of corresponding output, while at low loads the difference between the two types is not very noticeable. Mr. SWINBURNE's reply to the attack was far too brief, and he sometimes stands in danger of being regarded as an electrical LABOUCHERE, quaintly critical, but not to be taken seriously. The defects in the wattmeter which Dr. FLEMING discovered are more easily remedied than those of the transformers, since they are less obscure; and the Parthian shot in Dr. FLEMING's reply, at the use of a condenser for supplying the magnetising current, must not be considered to put this appliance *hors de combat* until further information is forthcoming.

The most novel part of the Paper is that which refers to the action of transformers at the moment of switching them on or off the mains. The sudden rush of current and the increase of voltage occasionally arising in this way is a remarkable fact, the truth of which was confirmed in the discussion. As, however, we have already pointed out, it is only the increase of voltage which is of any practical importance. The sudden rush of current cannot produce any dangerous amount of heating, for it only lasts for a small fraction of the time corresponding to the alternation of the current, and even if the maximum value of the current is twenty times as much as the ordinary magnetising current it does not exceed the full load current of the transformer. The rise of pressure may, however, manifest itself in a disagreeable manner, by damaging a voltmeter or by breaking down the insulation of the transformer which is being connected with the mains, or by piercing the cable or other weak point in the circuit. Dr. FLEMING's explanation of the rush of current appears sufficient, but his account of the manner in which the rise of pressure occurs is rather bald, and the matter seems to need further examination.

This protracted discussion gave rise, however, to a matter of more practical importance than anything mentioned in Dr. FLEMING's Paper. This was the reference made by Mr. CROMPTON to the losses which arise in the mains and feeders. The subject was further alluded to by Mr. ARTHUR WRIGHT, and Dr. FLEMING took up the matter in a very spirited fashion in his reply, and both he and other advocates of alternating currents seemed to think that his conclusions involved a signal defeat of the continuous-current system. His assumed load-factor may be accepted for the purpose of the argument, bearing in mind that motors are coming into use on continuous-current circuits, and that no simple alternate-current motor is yet on the market. Dr. FLEMING then finds that with a pair of 24-kilowatt feeders a mile long, one carrying a continuous current with a 40 per cent. drop of voltage on full load, and the other supplying six 6,000-watt transformers with a 2 per cent. drop, the efficiency is precisely the same. He finds, of course, that the "Hedgehog" transformers as supplied to him were out of the running. It would be too much to expect Dr. FLEMING to calculate a fourth case, viz., an open-circuit transformer as calculated and described at Newcastle, since that would only have been a hypothetical matter; but, after all, six 6,000-watt transformers supplying a low-pressure network is still a hypothetical case. In the practice of to-day transformers are placed in the customers' houses, although everybody talks about transformer sub-stations. We are not informed whether the transformer in this calculation was intended for sub-station work or no; open-circuit tranformers, at all events, may be specially calculated for such work.

While carefully maintaining an impartial attitude towards the rival systems, we cannot but think that Dr. FLEMING has blessed where he had been expected to curse, and that the result of his calculations is all that most continuous-current men want to confirm their convictions, while it all but fulfils the claims of the most ambitious advocates of low-pressure supply. Mr. CROMPTON has never discussed a greater length of feeding main than 2,000 yards, and in his Paper of April, 1888, he compared two mains of this length, with such data as were then available. Dr. FLEMING's mile is only 12 per cent. less than this. In commenting on Mr. ARTHUR WRIGHT's dictum that there is no room for a transformer within a radius of one mile and a quarter from a generating station, we remarked that advocates of continuous-current supply had never contemplated the supply of so large a district, and that only two London supply companies and three provincial stations out of twenty-four from whom we have received information, work at a greater radius than this. The ardent alternate-current men seemed to jump to the conclusion that because the losses were balanced according to calculation, *at the end* of a one mile feeder, a circle of this radius defined the district beyond which no continuous-current supply could hold its own. But the supply only *begins* at the end of the mile, and beyond this the low-pressure network extends just as it does round every continuous-current station in the country. The Westminster Company supplies Hyde Park Corner from Eccleston-place and from Davies-street, about three-quarters of a mile distant from either, so Mr. ARTHUR WRIGHTS' mile and a quarter as the radius of supply seems to be more than confirmed by Dr. FLEMING's one mile radius of feeding. On the other hand a radius of one mile from the Bankside or from the Wool Quay stations of the City of London Company em-

Hosted by Google

braces the whole of the City and plenty to spare. We do not wish to push Dr. FLEMING'S arguments too far, but it really seems, that from this point of view, the City would have been better served by continuous current! That there is plenty of room for alternating currents nearly everybody will admit; and many companies who have adopted this system, even though their farthest lamp—to say nothing of their feeding points—are within a mile from the station, are well advised in their choice, since their business will extend. In some cases the station being outside the town, alternating currents are almost indispensible, even though the consumers are debarred from electric motors (unless, indeed, mathematical literature on the subject will satisfy them), and though they are placed at a great disadvantage in the use of arc lamps. We believe Dr. FLEMING has rather overdone his comparison, and we are loth to believe that the result is so greatly in favour of continuous currents as his calculations show.

NOTES ON SUBMARINE CABLE WORK.*

BY H. D. WILKINSON.

(Concluded from page 322.)

27. Cable Depots.—Part of the system of maintaining submarine cables consists in means for storing cable on shore at convenient centres, and in the establishment of depots where cable can be stored, tested, turned over, examined, made up in good condition and drawn from as required by the cable ships. The Government have two such depots, one at Woolwich and one at Dover; the Eastern Telegraph Company have cable tanks at Gibraltar, Malta, Suez and Perim; the Eastern and South African Company tanks at Cape Town and cable hulks at Zanzibar and Mossamedes; the Great Northern Company depot and tanks at Woosung; and the Eastern Extension Telegraph Company at Georgetown (Tasmania), Sydney, Hongkong and a large central depot at Singapore, where some eleven tanks are fitted besides boiler house, engine shop, serving shop and stores. The first step in this direction was the utilisation of the hulks of old sailing ships, moored in harbours most centrally situated to the system of cables.

The tanks on shore are usually built of riveted iron plates, similar to those on ships, and are bedded on blocks of granite or concrete and roofed in by sheds of light angle-iron girders and corrugated iron. The construction of the tanks at Malta is an exception, being built of concrete and opening at the top flush with the ground. The illustration (Fig. 93) represents the tank sheds at the Island of Perim, a military station at the Indian end of the Red Sea. Cables were first landed here in 1884, and the Island is now a point of call on one of the Suakim-Aden and one of the Suez-Aden cables besides having one cable to the Arabian and two to the African coast, making seven in all. The place has rapidly grown and will probably become as important, if not more so, as a port than Aden.

For transferring cable from the ship to the tanks a small hauling machine is used, consisting simply of a V sheave with jockey pulley (as in Fig. 96), intermediate gear of small speed reduction, and a V pulley for a rope or messenger to drive it. A machine such as this is fixed on a platform immediately over the tank into which cable is to be coiled, and by means of a rope is driven off a small steam winch below. In the Cape Town tank shed a vertical boiler and engine are permanently fixed for this purpose (*see* Fig. 94), while at Singapore a portable steam gear with boiler complete is mounted on a line of rails between tank house and wharf. This is like a portable steam crane with a winding drum instead of a jib, and has a V sheave for the rope to drive the hauling machines over tanks. When being transferred from ship to tanks cable is taken three or four times round the drum of this gear, which supplies the power to pull it from the ship some distance away to the front of the tank house, whence it is lifted to the tanks by the small hauling machine described. When simply turning over cable from one tank to another it is only necessary to drive the hauling machines over the two tanks, and experiments at this depot have proved it most convenient and economical to drive them by an electric motor supplied with current from a dynamo in the engine shop. Sometimes one cable is being taken aboard from the tanks and another ashore from ship at the same time.

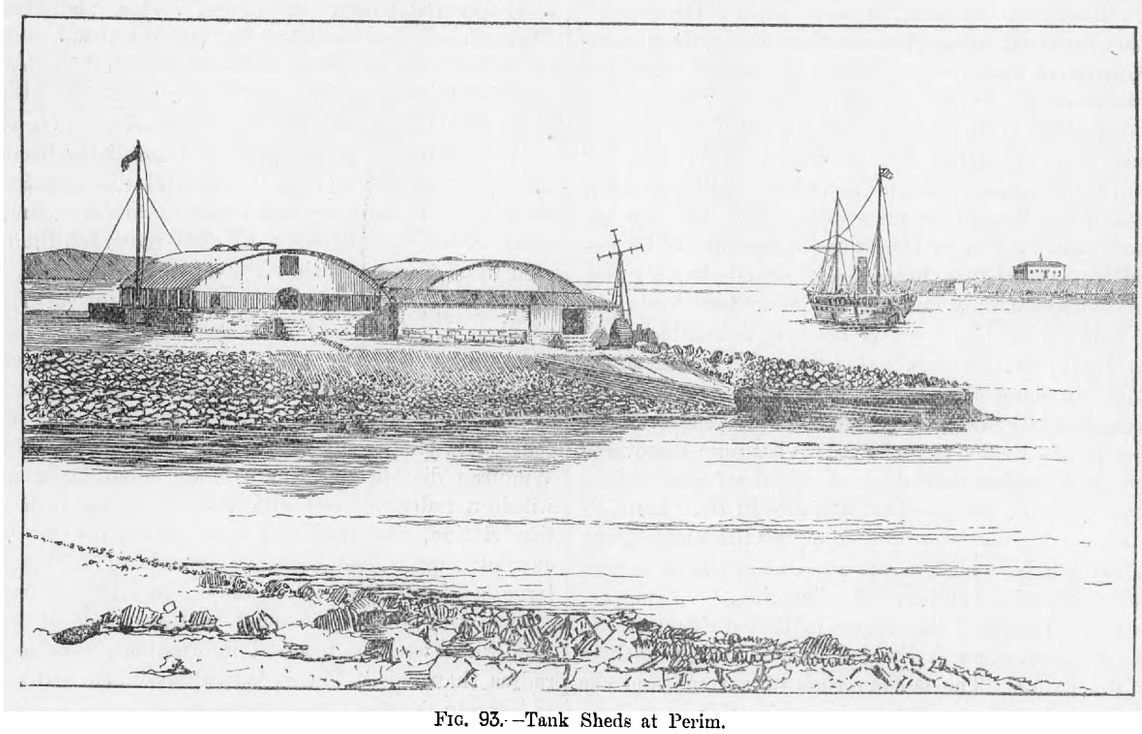

FIG. 93.—Tank Sheds at Perim.

The tank-shed at Cape Town (Fig. 94) encloses 6,000 sq. feet of floor space, and contains three tanks, one of 30ft. diameter and 6ft. deep, and two of 40ft. diameter and 8ft. deep. The total capacity to within one foot of the top is about 21,000 cubic feet, and deducting 4 per cent. for cone space, and allow-

* All rights reserved.

Hosted by Google

ing 40 cubic feet of coiling space per knot of type D, it is seen that the tanks will hold about 500 knots of this type of cable. Foundations of rough concrete 1ft. 6in. deep are prepared, and when properly set the tanks are got into position and held 2ft. above the floor by screw jacks, while a 1½in. layer of cement and sand is spread over the concrete bed. Before this has had time to set the jacks are lowered and the tank bedded and grouted in all round. The inlet and outlet water-pipes come in at the bottom of the tanks in the centre, and to facilitate drainage a layer of cement is run inside the bottom, tapering from 1½in. at the sides to 1in. at the centre. Cable is kept in its best condition when covered with water, but when turning over cable the water has to be discharged to allow the men to work inside.

A site is always selected as near as possible to where the ship can be moored, so that cable can be transferred easily. The Cape Town tank house is built on the promontory of land from which the new breakwater starts, immediately overlooking the docks and within 100 yards from where the ship can be berthed. To ship cable from the tank house or *vice versâ*, pairs of legs are rigged up every 20 yards and guyed, and a wire rope stretched along the top of them from tank house to ship. The cable then runs on V sheaves suspended about 10 yards apart on the wire rope, as in illustration. Where it enters the tank house the cable passes between a pair of vertical rollers, as in Fig. 95, and then passes over a sheave fixed to a bracket on the inside wall and thence to the hauling machine. The engine, a double-cylinder with reversing gear, transmits the power through mitre wheels and a vertical shaft to the hauling machine above, the speed being reduced about eight times.

A completely fitted testing room with concrete or brick and cement pillar for the reflecting galvanometer is also a part of the equipment of a tank house. Cable is overhauled at the depots and tested; if condemned the sheathing wires are stripped off and the core stored; if passed, the separate lengths of similar type are joined up and if necessary re-served. The process of re-serving consists first in running the cable—thoroughly dried—through a mixture of Stockholm tar and resin and then "parcelling" or taping over the sheathing wires with canvas strip. Over this is put a layer of soft compound and then another tape in the opposite direction to the first and finally a smear of hard compound. The latter is Bright and Clark's compound consisting of mineral pitch, tar and silica made from calcined flints ground to a powder, the object of which is to resist the attacks of the teredo by damaging its boring tool. Outside all, the cable is whitewashed as it is coiled in the tanks to prevent the turns from sticking together, as it would be dangerous for the men in the tank were this to happen during paying out.

When taking cable aboard it is convenient to use a portable steam hauling machine which can be fixed to the deck alongside any tank into which it is required to coil the cable. The tractive power is then just where it ought to be and as delivered from this machine the cable has only to fall by its own weight into the tank, where men receive and coil it. In a machine for this purpose a faster running engine can be used than with the ship's picking-up gear as there is no strain on the cable. When loading up from the factory a high-speed horizontal engine is sometimes fixed to the deck temporarily to drive a small hauling machine, but it would be inconvenient to have the two things separate when out abroad. A combined hauling machine coupled direct to a small high-speed Brotherhood steam engine has been brought out by Messrs. Johnson and Phillips, for which all the preparation necessary is to make an inch steam connection to the donkey boilers, generally a flexible steam pipe.

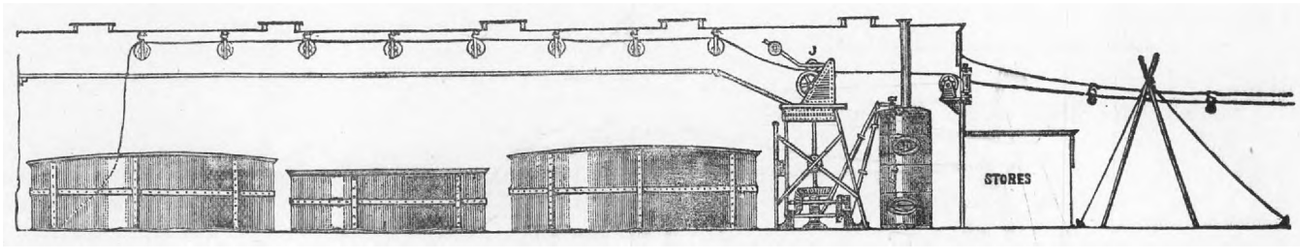

FIG. 94.—Tank Shed at Cape Town.

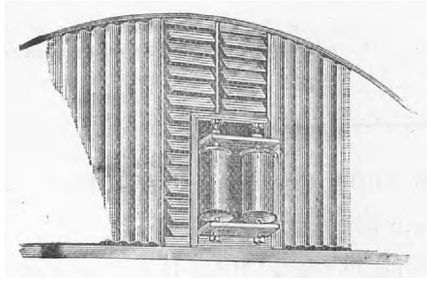

FIG 95.—In-leads to Tank House.

28. The Cable Ship "Retriever."—This vessel (Fig. 96), belonging to the West Coast of America Telegraph Company, and stationed at Callao, Peru, attracted public notice during the Chilian revolution of 1891, when the cables of this Company connecting the principal ports of Chili were cut and interfered with by war vessels of both parties. She was built on the Clyde in 1878, and passed her third survey under the regulations of Lloyd's Committee in 1891. Her principal dimensions are 180ft. by 30ft. by 16ft. deep; gross tonnage 775, and horse-power 95. She carries two tanks, each of 26ft. diameter, and 7ft. deep, having, therefore, a capacity of 200 knots of deep sea cable. The Company's system of cables kept in repair by this vessel run from Chorillos, near to Callao and Lima (Peru), down to Valparaiso, in Chili, touching at the intermediate ports of Mollendo, Arica, Iquique, Antofagasta, Caldera, and Serena. The total length of these cables is 1,700 knots. During the revolution, the war vessels of the Congressionalists cut the Mollendo-Arica and Arica-Iquique sections in one day; two days later the Iquique-Antofagasta section, and five weeks later that between Antofagasta and Caldera. As soon as the existing condition of affairs permitted, the "Retriever" proceeded to pick up the eight ends, and put them through, and including about 700 miles steaming had

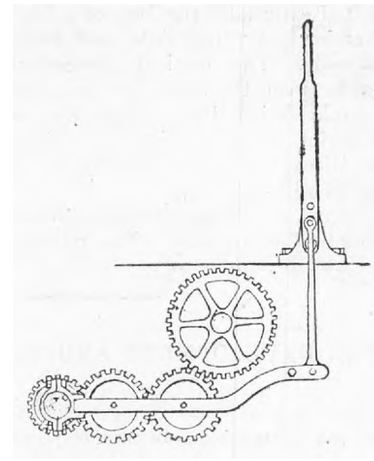

FIG. 97.—Gear for Driving Hauling Pulley.

Hosted by Google

the cables in working order within three weeks' time. The illustration is from a photograph of this vessel kindly lent by the Company.

29. **Cable Gear on the "John Pender."**—This vessel belonging to the Eastern Telegraph Company was fitted in the spring of 1890 with the new cable gear illustrated in *The Electrician*, Vol. XXV., p. 198. In this gear, designed by Messrs. Johnson and Phillips, the two drums are quite independent, being connected to independent trains of gear, each having a double purchase by which the ratio of engine speed to drum speed can be made either 100 : 3 or 100 : 6. There are also two independent engines, but by means of a connecting clutch between the two first motion shafts either engine can be made to work either drum or both.

The engines are by Messrs. Robey and Co., and, as will be seen in the engraving, are double cylinder verticals. The support to the cylinders in each engine is in two castings, bolted together with front and back plates, forming a hollow framework, in which the crank shaft revolves in oil and water. This framework forms internally the guides for the crossheads, and to it are bolted externally the brackets for valve spindle guides and reversing gear, the links and excentrics for the latter being outside. The vertical space occupied by the engines and gear between the main deck and bridge is about 6ft. 6in., the stroke being 15in. Sight-feed lubricators are fitted to each engine. The holding down bolts are secured underneath the deck, which is of iron, by 8in. baulks of timber and large plate iron washers.

The starting valves, reversing gear and brake wheels are all operated from the bridge platform. The hauling-off pulley is thrown in or out of gear by lever (Fig. 97). When it is required to disconnect and run the pulley on the brake as in paying out, a pin is removed, and the lever is let down. A separator is fitted to the steam pipe supplying the engines, and all water drained off here is returned to the boilers by a pipe arranged on the principle of the steam loop.

Steam used for working the cable gear, electric light engine, winches, and Gwynne's circulating pump, is all condensed and returned to the boilers. The common exhaust from these engines is taken to one of Kirkaldy's condensers, the circulating water for which is supplied by the Gwynne pump. This condenser delivers the fresh water into a tank, from which it can be sucked into the condensers of the main engines by the vacuum, and thus worked round again to the boilers by the air-pump, hot-well, and feed-pumps. The small deficiency is made up in the usual way by sucking in a little sea-water into main condenser from delivery side of main circulating pump, where it mixes with the condensed steam, and is pumped up into the hot-well.

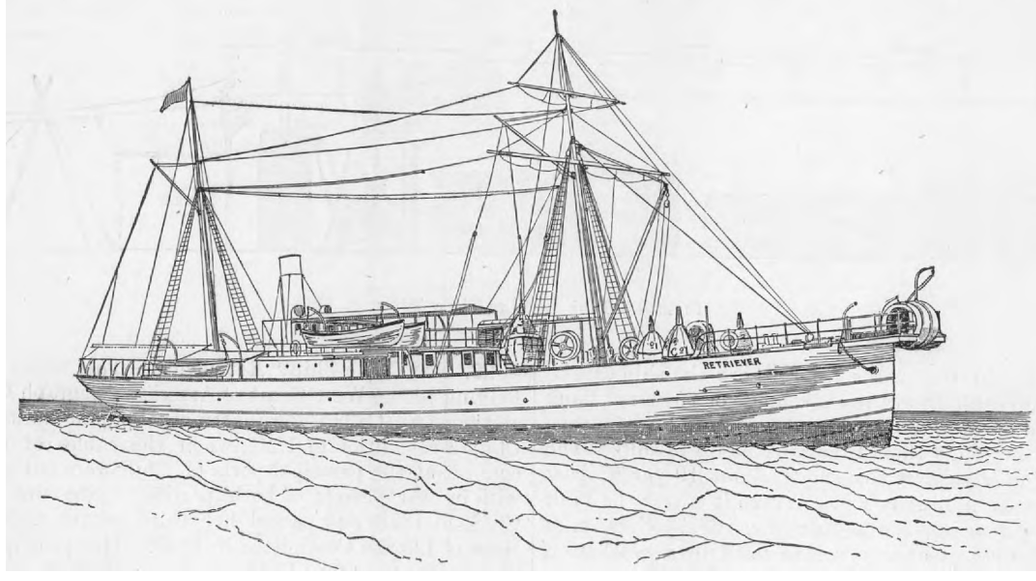

Fig. 96.—Cable Ship "Retriever."

The work of repairing cables has now been treated upon in detail and in simple form, and different types of ships and gear described up to date. In the concluding portion the author intends treating upon modern electrical tests for localisation of faults, also cable laying operations, including the surveying of routes, sounding apparatus, ship and shore tests, and the landing of shore ends.

[*This series of articles will be suspended owing to the author's absence abroad. We hope the series will be resumed in the course of our next volume.*]

THE DEVELOPMENT AND TRANSMISSION OF POWER FROM CENTRAL STATIONS.*

BY PROF. W. CAWTHORNE UNWIN, F.R.S.

The suggestion that transmission of motive power to a distance could be effected by air was an old one. As early as 1845 at some mines in Belgium power was transmitted 750ft. by compressed air. A great impetus to the use of compressed air as a means of power was its application to the working of boring machines in tunnels. Compressed air was used in the boring of the Mont Cenis tunnel. The machines first employed were very inefficient. From that time the use of compressed air in mining operations made very rapid progress. In 1877 Mekarski used air compressed to 25 or 30 atmospheres, in conjunction with a small amount of high pressure steam to drive tramway cars, and the Mekarski cars were still running in Paris. Mekarski was amongst the first to use a compound compressor.

Hughes and Lancaster Compressed Air Tram.

Whilst speaking of tramways, he might say that a rather interesting system of compressed air tramway had been invented by Messrs. Hughes and Lancaster, at Chester, which seemed efficient in certain cases, and which might be a solution of the problem of tramway traction. There was no application of motive power which had proved more difficult than the working of tramways. The cable tramway did admirably well when there was a large enough traffic, but a very large traffic was required to make the system pay. The steam tramway was a dreadful thing. Electric tramways existed only in the shape of tramways with overhead

* Howard Lecture V., delivered before the Society of Arts, Friday, February 10th.

Hosted by Google

conductors, and although in America they had an extension of 4,000 miles, that form of tramway did not seem to be adapted to this country. In the system which Hughes and Lancaster had adopted they had on the tramcar an arrangement for obtaining, almost automatically, a charge of air at charging stations a quarter or half a mile apart. The apparatus on the car was attached to a pipe, which, as the car passed over the charging station, went down into a pipe placed in an ordinary manhole at the side of the tramway, forced open a valve, and took its charge of air. He experimented with that system some time ago, and it really gave good results. The car experimented with was an old ordinary horse-tramcar with reservoirs containing 50 cubic feet crammed underneath it in a very uncomfortable position. The air available was only 150lb. pressure, but the car worked very well. The engine on it was a Rigg motor, and it worked exceedingly well, except for one thing: the valves were not tight, and there was a good deal of leakage, which was against the favourable action of the car. However, starting with a pressure of 150lb., it ran distances of from 600 to 1,500ft., with a full load of passengers, weighing about six tons, on gradients varying from level to 1 in 45. On a special trial the car ran 1,230ft. up a very steep hill, with gradients varying from 1 in 130 to 1 in 24. He did not think that particular application of compressed air was very well known, but it seemed to him exceedingly likely to be a very useful application.

The Advantages of Compressed Air.

Compressed air was a perfectly general mode of transmitting motive power. Whether in any particular case it was the most advantageous, the most economical, the one which would cost least in installation, might be a question; but it could be used in all cases, even when the distance of transmission was very great. The air mains could be carried by any path, however winding and broken, and the method had the advantage that differences of elevation between the generating station and the motors did not affect the efficiency of the arrangement. In hydraulic transmission the water must be collected, generally stored, sometimes bought, and arrangements must be made for getting rid of the water. In a compressed air system they got air anywhere for nothing, and it was discharged anywhere without nuisance. Compressed air had obviously very great advantages in the case of underground transmissions. It might replace manual labour where hardly any other mechanical agent could be employed. In boring a tunnel, for instance, the saving was so great, even with uneconomical machinery, that there was no great inducement to improvement, and in those cases cheap plant was more important than efficient plant; hence much of the compressing plant used in mines was extravagantly wasteful in power. In many cases the machines were worked by water-power, and this again militated against attention being paid to economy of working. It was only lately, as compressed air had been adopted as a means of distributing power in towns, that any careful consideration had been given to the question of economical working. The earlier and rougher applications of compressed air had given ample ground for the popular opinion that the efficiency of compressed air transmission was exceedingly low; probably in many cases it did not exceed 20 per cent. In great towns like Paris and Birmingham attention had been given to economy, and better results had in fact been obtained; but in both those cases the conditions under which the works had been carried out had been disastrously unfavourable to a complete trial of compressed air. In cases like Geneva and Zurich, where they had an abundant supply of water-power, where reservoirs could be constructed at a sufficient but not excessive height, hydraulic transmission had great advantages; but in the much more numerous cases where these local conditions were not present, compressed air transmissions were likely to play a considerable rôle.

Compressed air was the most formidable rival of the electrical transmission of power. For ordinary power purposes, excluding the application of power for transit and lighting, probably at this moment, enormously more work was being done by compressed air than by electricity. There were a few cases where power was distributed for industrial purposes by continuous current electrical systems. Such systems were perfectly effective, but too costly. Electricians told them the alternating system would be much cheaper. At present there was no case where power was distributed by the alternating current system; there were only certain elements of such a system which might be employed in the future. From the standpoint of past experience it might be asserted that power distribution in towns, in cases where the distribution was not merely a subordinate function of a plant intended primarily for electric lighting, especially in cases where the work had previously been done by steam engines which could be converted into air motors, could be more economically and efficiently effected by compressed air than by electricity.

Air Compressors.

With regard to the general arrangement of a system of compressed air distribution, it consisted first of a compressing plant, worked often by a steam engine or water power. Then there was provision for a certain amount of storage of compressed air. Secondly, there were the mains for conveying the air to the working points; and thirdly, the motors actuated by the compressed air. These were provided sometimes with re-heaters and other arrangements for increasing their efficiency. They had, therefore, to deal with the three different considerations of the compressors and their efficiency, the mains and their efficiency, and the air motors and their efficiency.

In the compression of air, in an air compressor, the principal practical loss which arose was due to the heat generated in the process of compression. In ordinary cases during compression, the air was considerably heated. If the air motor worked close to the air compressor, that involved no particular loss. But generally the air had to be conveyed to long distances. In that case the air cooled down before it was used, and the whole of the work expended in generating heat in the compressor was for practical purposes lost. The ideal compressor for power distribution would be one in which the compression was isothermal. The heat losses increased rapidly as the pressure to which the air was compressed was greater. It increased nearly as the square of the ratio of the pressure of the compression to the atmospheric pressure. There was no doubt this rapid loss of heat had led to the use of comparatively low pressures for compressed air in a great many cases. This involved an oversight. With the higher working pressures the increased loss of the compressing plant was largely balanced by greater efficiency of the motors, so that although in compressing to high pressure they lost more in heat, their air motors worked more efficiently, and part of the loss was made up.

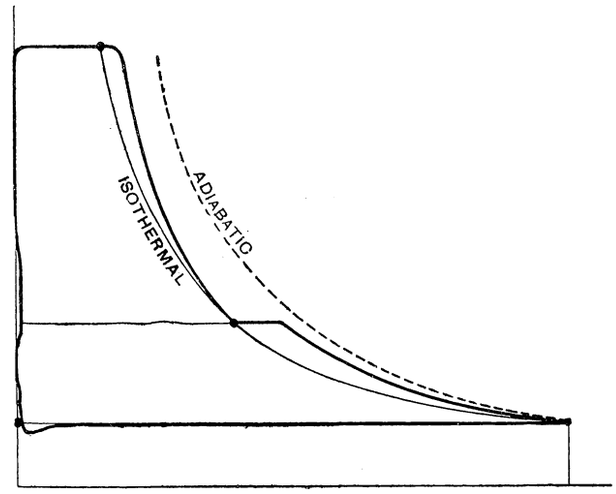

FIG. 1.—Compression Diagram of Riedler Compound Compressor.

Various means had been adopted to cool the air during compression. Some had replaced the jacket of the air chamber with a cylinder through which cold water passed. This had disadvantages, for the surface was small for the heat produced, and air did not readily part with its heat to a metallic surface. The employment of a water piston had some effect in cooling the air, and the wet cylinder walls in a compressor worked with a water piston absorbed heat rather more rapidly than the dry metallic walls in an ordinary compressor. But the best direct means of cooling air during compression consisted in ejecting water into the compressor in the shape of fine spray; a method first proposed by Prof. Colladon in the works for the St. Gothard tunnel. There was another method of obviating a great deal of the heating losses, which was to use a compound compressor. By whom the compound compressor was first used he did not know; it was certainly used by Mekarski for comparatively high air pressures at a comparatively early date, and at any rate as early as 1880 it was used in America in ordinary mining compressing plants. He believed in some of the early compressors which were made compound, the object was merely to equalise the piston load, but it was very soon found, as would be seen from Fig. 1, that the compound compressor gave means of annulling the greatest part of the heating loss.

The earliest compressors, which did at all a tolerably good duty were water piston compressors. In one of the St. Gothard tunnels water piston compressors, made by the Humboldt Company, a ram worked into two cylinders, and at each end they had a water piston. This was in many respects an exceedingly efficient compressor. Its defect was that it could not be run at a greater piston speed than 100ft. permanently, and therefore it was a very large and costly compressor for the amount of work it did. That compressor got laid aside simply because it was too costly. It was superseded by compressors which worked with a spray injection, such as that of François and Dubois, which could be run at two or three times the speed of the water piston compressors, therefore it was a

Hosted by Google

much smaller machine for a given amount of work and very much less costly. By far the largest number of compressors used in mines and so on were compressors of this type, but although they gave a discharge of comparatively cold air, the cooling effect of the spray was not quite so great as it appeared to be. A good deal of the cooling went on too late in the stroke, and the compression curve was not lowered so nearly to the isothermal curve as it ought to be if the cooling took place earlier in the stroke. The effect of the spray was a little deceptive. They could not get a better result, however, except by resort to the compound compressor. The compound compressor in itself was a more expensive machine, and it became in that case particularly desirable to reduce as far as possible the size of the machine for the work it had to do. That could only be done by adopting arrangements whereby a compressor could be run at a high piston speed, and to secure that Prof. Riedler had introduced in the compressors constructed under his instructions, especially in the large 2,000 H.P. compressors in Paris, a system of mechanically moved valves. He was in the compressor house in Paris a few months ago. It really was a very fine sight indeed. They had there four triple steam engines, each of 2,000 H.P. Three of them were working continuously. For a few hours at night only one of them worked, he believed, but during the greater part of the day three of them worked at a speed of 40 revolutions a minute. Towards evening, when the compressed air was being largely used for electric lighting, the engines were speeded up and ran at a speed of nearly 70 revolutions. He believed they would run perfectly well at 80 revolutions, and it was on record that through some mismanagement the engine once ran nearly up to 200 revolutions a minute. A 2,000 H.P. engine running at that speed was not seen every day.

Compressed Air Mains.

He now came to speak a little of the losses in transmitting air from the generating station to the working point. First of all, it was to be noted that the frictional resistance in pipes containing fluid was proportional to the density of the fluid. Consequently at equal velocities the friction of air flowing in the mains was enormously less than that of water. In air mains there was nothing analogous to the hydraulic shock which so very much limited the speed at which water mains could be worked. In air mains velocities of from 30 to 50 feet per second were allowed without serious frictional loss, and it was this high velocity which enabled them to transmit at moderate pressures, with engines of moderate size, a very large amount of power. The author had pointed out that hydraulic 6in. mains, working at 750lb. pressure per square inch, at a velocity of 3ft. per second, would only transmit 90 utilisable H.P., allowing for losses at the motor. Air at 45lb. pressure in these mains, with a velocity of 50ft. per second, would transmit nearly twice as much. The largest hydraulic mains were 7in. in diameter, but air mains could be constructed of any size. In Paris there was a main 7 kilometres in length, which was 24in. in diameter and transmitted 6,000 H.P. In the older Paris mains, which were carried chiefly through the sewers, and had an exceptionally large number of bends, draining boxes, and other sources of resistance, and in which the velocity of the air varied from 25 to 30ft. per second, the frictional loss only amounted to 2lb. per square inch per mile of main. As to the exact way in which the resistance of the air mains influenced the efficiency there was still a word to be said. Supposing the main received air at 60lbs. gauge pressure which reached the other end at 55lbs., then there was 5lb. loss due to friction. It was commonly assumed that as there was 5lb. loss out of 60lb. 5-60ths of the energy of the air was wasted. That was altogether erroneous, and was based on a false hydraulic analogy. The expansion of the volume of the air largely compensated for the loss of pressure. The frictional loss was only indirect, energy at 55lb. being not quite so available as the same amount of energy in an equal weight of air at 60lb. pressure. He would not go into the exact calculations, but would mention that in the case he had considered, where there was a 5lb. loss in 60lb., instead of the loss being 5-60ths, he had found by calculation that the real loss was about 3 per cent. For short distance transmissions the consideration just stated was not perhaps very important, but the principle involved became important when long distances had to be considered. The author believed that it could be shown by data, verified by experiments on a line over 20 miles in length, that long distance transmission by compressed air was perfectly practicable; it was quite possible to transmit 10,000 H.P. by an air main of not unusual size to a distance of 20 miles, and to use the compressed air for motor purposes, obtaining an efficiency of 40 and 50 per cent. if the air were used cold, or 70 to 80 per cent. if the air were, as it ought to be, re-heated before use.

Now, he should like to say something about the construction of the mains. Unfortunately fo the compressed air system, a very large and very interesting installation at Birmingham had completely failed. One ought not to speak ill of the dead, and he was not going to say much, but, certainly, he thought there the most serious engineering mistake made was in attempting to transmit compressed air through steel mains with ordinary lead joints. In those mains the air went in at one end during a great part of the day at a temperature of 280deg.; they were heated up to 280deg. once a day and cooled down at night to a much lower temperature. No ordinary joints would stand that action, and the result was that there was a continual leakage, and a very large leakage before the installation finally expired. There was at the time that installation was carried out a perfectly successful air main in Paris with perfectly simple joints in which there was no appreciable leakage. The pipes in that case were plain spigot-ended pipes; a kind of ring was placed over the joint (*see* Fig. 2.); against each end of the ring there were two india-rubber washers, which were pressed against the ring and against the pipe by two clips. That was a perfectly successful joint; it allowed an expansion at every length of the main, and it allowed the main to bend if there was a settlement of the ground without any harm. The only question raised about it was whether india-rubber joints were durable. The joints were arranged so that the rubber was nowhere exposed to the air. So far as experience went, and it extended over a number of years, the joints were found to have the india-rubber in perfectly good condition, in fact as good as when they were put down. That joint was now being used in all important new air compressing arrangements. The Paris main, and still later the Offenbach main, showed that they could have a compressed air main in which the leakage was an absolutely insignificant quantity.

Compressed Air Motors.

The air motor was essentially a reversed compressor. It was free, however, from the heating which caused so much difficulty in the compressor. The air cooled in expanding, and in some cases this gave rise to difficulty from the production of ice. Some special air motors of simple construction and small size were used in Paris, but most air motors were simple non-condensing steam engines adapted to the use of compressed air. Probably the greatest source of inefficiency in the air motors was leakage, especially piston leakage. In steam engines condensation helped to keep the piston

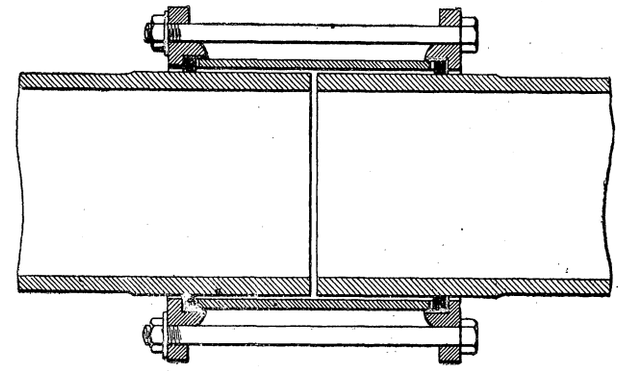

FIG. 2.—Paris Compressed Air-Main Joint, with India-rubber Washers.

tight. In air motors they had dry pistons, and therefore the leakage was a more serious difficulty. Unfortunately he did not think anyone had set to work to see exactly how a proper air motor ought to be constructed. But in the case of air motors now used in Paris they had efficiency data. In the very small and imperfect rotary motors used in Paris the consumption of compressed air was about 750 to 850 cubic feet of air compressed to five atmospheres for each effective horse-power hour. In the old steam engines converted for use as air motors the consumption was 450 cubic feet of air compressed to five atmospheres for one effective horse-power hour. In the new compressing station on the Quai de la Gare they compressed a cubic metre of air —that was at 7 atmospheres, but that fact might be overlooked— for 0·4 of a centime. Suppose they allowed, as careful estimates for the waste of the installation showed to be sufficient, that they compressed air at 0·4 of a centime per cubic metre and charged for it 0·7 of a centime per cubic metre, to allow for interest and depreciation on compressing and distributing plant. He found on that basis that in Paris the cost worked out to nearly 1d. per horse-power-hour for the small and extravagant rotary motors, and ½d. for the old converted steam engines used as air motors. In the latter case the cost corresponded very nearly to £6. 5s. per effective horse-power per year of 3,000 working hours. He thought there was no question that still better results would be attained very soon, when motors were built expressly as air motors, and in the most suitable form in which air motors could be used.

The amount of expansion which could practically be permitted in the air motor without inconvenience from the excessive fall of temperature in expansion was limited. It varied with the dryness of the compressed air and with some other conditions, but a practical limitation of the efficiency of the air motor was thus imposed. All difficulty arising in that way was obviated by re-heating

Hosted by Google

the air before it was used in the motor, and this added to the mechanical work obtained. Part of the heat applied was transformed into work, and the given quantity of air supplied did more work. As the motor was charged for by quantity of air consumed, the cost of the horse-power hour was thus diminished. Whether it was economical or the reverse to heat the air before using it in the air motor depended upon whether the value of the additional work done was more than the value of the coal or other fuel employed in heating the air. General experience had shown that it was extremely advantageous and economical to heat the air before using it. This arose partly out of the circumstance that heat so applied was very efficiently used, and a very much larger fraction of it was converted into work than in ordinary heat engines. The desirability of heating the air being conceded, it remained to consider whether it was troublesome or involved costly apparatus. Experience showed that extremely small, easily managed, and simple furnaces could be used in heating the air. According to Prof. Riedler's experiments, the heat thus used was five times as efficient as an equal amount of heat in an ordinary steam engine. They had in Paris tried a slight improvement. As air did not very readily take up heat from metal surfaces it was advantageous to introduce a small quantity of water into the spiral pipes of the re-heater; this water took up heat readily; it was converted into steam, and passed with the air into the motor. Some years ago he suggested in connection with air transmission that the proper way of using heat in compressed air transmission was to burn the fuel in the current of air. His friend Dr. Sellers took the suggestion to America, and someone had tried it there in a crude form with a petroleum lamp (*see* Fig. 3). Another suggestion was made at Dresden of working gas engines in conjunction with air motors, the heated products of combustion in the gas engine being taken through the jacket of the air motor, and conversely the air going to the air motor being taken through the jacket of the gas engine. In the use of compressed air in town distribution there was no difficulty in measuring the quantity of air used by each consumer. There were perfectly simple forms of meter by which the quantity used could be quite accurately ascertained.

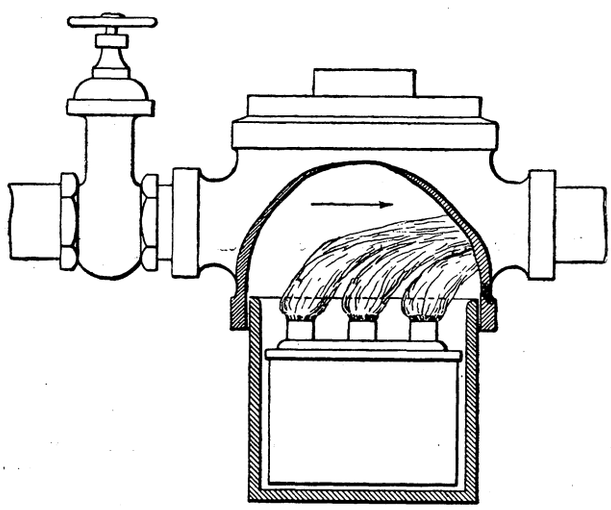

FIG. 3.—Petroleum Lamp Re-heater for Compressed Air Main.

The Paris and Offenbach Compressed Air Systems.

The Paris system of compressed air power distribution was the largest in Europe. It developed out of very small beginnings. First it was merely a system of regulating clocks by impulses of compressed air. In its earliest condition there was a reservoir with air at two or three atmospheres pressure. There were two clocks which actuated valves which sent a pulse of air lasting for 20 seconds once in every minute through the mains. In 1889, 8,000 clocks were driven and regulated from the central clock by the pneumatic arrangement. The system proved very successful, and a new station was built. In 1887 a demand arose for compressed air for working small motors, and a large extension of the system was made. A second installation was erected, and in this were placed Davey Paxman engines, the whole of the steam engines aggregating 2,000 H.P. Very soon that installation became insufficient. A third installation was added to the station in the Rue Saint Fargeau, consisting of five compound engines and compressors built by Cockerill, that also worked at 2,000 H.P. Finally a fourth installation was constructed, designed initially to work to 24,000 H.P. Part of that station had been erected at the Quai de la Gare on the Seine some distance above Paris, and that was a station where they now had 8,000 H.P. The air was used for the most various purposes. At some of the theatres and restaurants it drove dynamos for electric lighting; at the printing office of the *Figaro* there was a 50 H.P. motor, and at the office of the *Petit Journal* a 100 H.P. motor; and in numerous workshops the power was used to drive small motors. It was used also for producing cold in extensive refrigerating stores. There was one electric lighting station worked by air motors in which were eight 50 H.P. air motors. Up to the time of the beginning of the new central station the system had been worked with considerable success. In the new station they adopted Riedler's large compound compressors in the place of the François-Dubois compressors, and they used triple steam engines working at 180lb. pressure, and the effect of this and of other arrangements for economy was that they obtained a cubic metre of air for four-tenths of the cost for which it had been previously obtained. The cost of working the new station as compared with that of the old one was so low that he believed that the old one was not now used. Unfortunately, at the present moment the Paris Air Company was in more or less considerable difficulty. So far as he could learn, the supply of power by compressed air was, on the whole, a perfectly successful operation; but the Company was hampered by the fact that the compressed air power distribution was associated with a very unremunerative electric system, and while the distribution of compressed air was fairly successful, the very costly electric-lighting stations, which also belonged to the same company, were worked far less successfully.

At Offenbach, near Frankfort, there was, probably, the most perfect compressed air distribution which had been hitherto constructed. It was not a very large station, but its arrangements throughout were as good as, with the present knowledge, they could be. The station had been working for about a couple of years delivering compressed air through about 23,000ft. of mains. Those mains had been tested for leakage, and the loss by leakage in the whole of that length of main with a pressure of six and three-quarter atmospheres was only one and a-half cubic feet per mile per hour.

EXPERIMENTAL RESEARCHES ON ALTERNATE CURRENT TRANSFORMERS.

The following is an abstract of the discussion on Dr. Fleming's paper, which took place on Thursday evening last week, at the Institution of Electrical Engineers. Speakers whose remarks are prefaced by an asterisk have returned their proofs revised :—

* Prof. AYRTON did not think Dr. Fleming quite understood the way in which it was proposed that the three voltmeter method should be used. It was not proposed that every time they wished to measure the power given to an alternating current circuit the three voltmeter method should be employed. But it was intended that the accuracy of wattmeters, &c., might be checked by means of this method. He wished also to point out that Dr. Fleming's description of the method of testing transformers used at the Central Institution did not adequately describe it; for first, it was essentially a workshop method, secondly, it gave directly the losses in the transformer, and thirdly, it separated the iron and copper losses, each being read off directly on a wattmeter. Throughout the paper Dr. Fleming used the abbreviations P.D. and ammeter, and so by winning the hearts of the proposer of those abbreviations, all criticism had been almost disarmed on his part. He had noticed that P.D. was called slang in one paper; it was *The Electrician*. He supposed "Salisbury-court, E.C.," would be also slang; he thought of writing to say so, but remembering that "W. E. Ayrton", and all other abbreviations would be slang too, he refrained from doing so. He ventured to propose another abbreviation. He proposed to drop the expressions virtual current and effective current altogether, and to use abbreviations for the particular things they wanted to measure. The D'Arsonval galvanometer for instance measured the mean current. Let this be called the M. current. An ammeter with a soft iron needle, or an electro-dynamometer, measured the mean square of the current. Let that be called the M.S. current. If the dynamometer were graduated so that the square roots of the deflections were taken, allowance being, of course, made for the variation of constant at different parts of the scale arising from the distortion of the spring, then they got what had been unwisely called the effective current, or the virtual current; it was really the root of the mean square of the current. He proposed, therefore, to call it the R.M.S. current.

Prof. PERRY hoped Prof. Ayrton would be allowed to leave out the latter part of his remarks in correcting his proof.

The PRESIDENT: He can do what he likes, sir; he generally does.

*Dr. FLEMING, in his reply, said that it often happened that at the end of a long discussion, the author of the Paper under discussion found that many of those who had spoken had answered one another's difficulties, criticisms, or objections. In the present instance, however, there were reasons for answering his critics, with some care and detail, and he would take the speakers in the order in which they had spoken.

Mr. Swinburne might be considered the chief defendant, and his first remark concerned his electrostatic voltmeter. Mr. Swinburne said his firm had considered the question of employing the oil damping arrangement suggested by the author, but preferred electro-magnetic damping. Mr. Swin-

Hosted by Google

burne's speech was made on Dec. 1st, and reported in *The Electrician* of Dec. 16th, and being marked by an asterisk as having been corrected by the author, might perhaps be taken to represent correctly what he stated when he took part in the discussion on Dec. 1st. On referring to *The Electrician* for December 2nd they would find a short article, having all the appearance of an inspired communication, in which the following statement occured, in speaking of the Swinburne electrostatic voltmeter :—"The electro-magnetic damping arrangement has been done away with, and an adjustable oil damper substituted, which enables any degree of damping desired to be obtained." His (Dr. Fleming's) Paper was read on November 24th, so that practically it came to this : Mr. Swinburne adopted and utilised the suggestions about oil damping on December 2nd, and repudiated them again on December 16th. With regard to the use of mica for preventing discharges from the cable to the case, it was quite true that they used the voltmeters for higher pressures than those for which they were originally designed, but they deserve every credit for thus converting an instrument arranged by its maker for 1,200 volts, into one which could be used up to 3,000. The only objection which Mr. Swinburne was able to urge against the use of mica for clothing the "needle" was that it rendered it impossible to calibrate the instrument from standard cells. The calibration of an instrument up to 2,000 volts, with standard cells, was an operation that required the very greatest care, in order to avoid serious errors, and he (Dr. Fleming) could not conceive how anybody could delibrately prefer that method to the exceedingly simple and effective one which he had described, employing a non-inductive divided resistance and a voltmeter working up to 100 volts. Coming next to the much-discussed wattmeters, it was admitted that the first wattmeter Mr. Swinburne sent was not correct, but that the second one was, and the only difference of opinion which existed was as to the cause of error. Mr. Swinburne still thought, judging from his printed remarks in the report of the discussion, that eddy currents in the case had something to do with this error. It was perfectly clear that he failed to notice in his (Dr. Fleming's) Paper a table of experiments in which that particular wattmeter was used with the case *on* and with the case *off*, and in which it was shown that the removal of the brass case made very little or no difference in the erroneous low readings of the wattmeter. Hence, it was perfectly evident that the substantial cause of error was not eddy currents in the case. The interesting figures which Dr. Sumpner had obtained from his own experiments, and from the analysis of the figures in the author's Paper, sufficiently showed that, at any rate, in that wattmeter practically the whole of the error could be accounted for by local currents set up in the brass plates which carried the series coil. In the next place, Mr. Swinburne objected to the term "power factor." It was very difficult to know how to please Mr. Swinburne in the matter of terms.

He now came to the real question at issue, namely, the question of open *versus* closed magnetic circuit transformers. Mr. Swinburne said that he (Dr. Fleming) had not settled it. No matter of the kind ever was settled. What he *did* claim to have settled was the fact that up to date the best open-circuit transformer that could be produced was not electrically better than the closed-circuit transformer of equal output. In order to properly test the matter, they must assume certain conditions of working, in other words, assume a certain load diagram, and then, on that load diagram, compare the all-day efficiencies of two transformers of equal nominal output, working under the same conditions. The figures in his Paper would enable them to do that for themselves ; but in order to bring home the facts, he had prepared a series of tables for the purpose of such comparison. He had compared together the all-day efficiency of a 6,000-watt "Hedgehog" and a 6,000-watt "Mordey" transformer when working on a 10 per cent. load factor. In Tables I. and II. he had compared the performance of the two transformers by making an energy balance-sheet for each transformer for the 24 hours. They would see from them that for the open circuit transformer the all-day efficiency was 74·2 per cent., and for the closed circuit transformer it was 74·3 per cent. Let them vary the diagrams as they pleased they would find that under all the ordinary conditions of work the 6,000-watt closed circuit transformer gave a slightly higher all-day efficiency than the 6,000 open circuit transformer, and that the accuracy of these figures could not be impugned. It was interesting to go a little further, and see how far the internal losses in the transformers were supplemented by losses in the primary main when the transformers were working on the same load diagram. He had, therefore, assumed a case, which was quite capable of being realised in practice, namely, a primary main a mile long, consisting of a 7/16 cable in each branch, and four 6,000-watt transformers placed at the end of that primary line. In Table III. were calculated out the 24 hours' loss in the primary cable for each case. In the case of the four "Hedgehog" transformers the 24 hours' loss in the line would be 2·659 units. For the four Mordey transformers the 24 hours' loss in the primary line would be 0·454 of a unit. If the total losses in the transformers and cable were taken for the 24 hours in the two cases, they found that while the four "Hedgehogs" plus cable dissipated 18·155 units, the four Mordey transformers of the same size and on the cable dissipated only 15·798 units, the secondary circuit delivery in both cases being 60 units. In addition to the cable losses there would also be the relative losses in the dynamo armature, but on calculation it would be found that, owing to the low resistance of modern armatures, the armature loss was really quite negligible. Was there, in face of this, any foundation in fact, whatever, for the statement so frequently made that they could afford to throw away their closed-circuit transformers, and replace them by the much more economical open magnetic circuit transformers. The difference between the total energy losses in the two cases in the 24 hours would amount to about 2·36 units, and in about 365 days that would signify a total of 860 units, which at 3d. a unit was £10. Mr. Swinburne proposed to remedy the defect of a large magnetising current by employing condensers, and had spent a considerable amount of time in developing a condenser for the purpose. It was a very important matter to ascertain whether the proposed remedy was really a remedy. Now, none of the condensers submitted to him (Dr. Fleming) for testing had proved themselves to be without dielectric hysteresis. For instance, a certain condenser submitted passed, at a pressure of 2,400 volts, a current of about four amperes—such a condenser would probably be used to supply current for four 6,000-watt "Hedgehog" transformers. That condenser absorbed 120 watts. Suppose that such a condenser were placed at the dynamo end of the primary line to supply the four transformers at the other end with magnetising current. Now, he very much doubted whether a condenser made of paper could be made to have a power factor of less than 0·01, and would be found to take up quite 100 watts in power. If this were the case, it was then obvious that in the 24 hours such a condenser would dissipate 2·4 B.T.U. of electric energy. The object of putting a condenser there at all was to save the line loss. If they looked for a moment at Table III. they would see that the loss in the

Table I.—*All-Day Efficiency of 6,000-Watt "Hedgehog" Transformer on a 10 per cent. Load-Factor.*

Let the load diagram be taken as equivalent to

$$24 = \begin{cases} 11 \text{ hours working at no secondary load} \\ 5 \quad \text{,,} \quad \text{,,} \quad \text{1-10th of full load} \\ 4 \quad \text{,,} \quad \text{,,} \quad \text{1-8th ,, ,,} \\ 3 \quad \text{,,} \quad \text{,,} \quad \text{1-4th ,, ,,} \\ 1 \quad \text{,,} \quad \text{,,} \quad \text{3-4ths ,, ,,} \end{cases}$$

which is equivalent to 2·5 hours at full load, or to a load-factor of *very* nearly 10 per cent.

The energy balance-sheet for the transformer on this load, as derived from tables of observations, is as follows :—

Energy in watt-hours given to primary circuit.	Energy in watt-hours taken from secondary circuit.
11 × 151 = 1,661	11 × 0 = 0
5 × 767 = 3,835	5 × 600 = 3,000
4 × 919 = 3,676	4 × 750 = 3,000
3 × 1,674 = 5,022	3 × 1,500 = 4,500
1 × 4,680 = 4,680	1 × 4,500 = 4,500
Total = 18·874 B.T.U.	Total = 15·000 B.T.U.

Energy loss = difference = 3,874 units in 24 hours.
Iron all-day loss = 24 × 151 = 3·624 units.
Copper all-day loss = 0·250 ,,
Total loss = 3·874

All-day efficiency on this 10 per cent. load-factor $= \frac{15{\cdot}000}{18{\cdot}874} = 74{\cdot}2$ per cent.

Table II.—*All-Day Efficiency of 6,000-Watt Mordey Transformer on the same above 10 per cent. Load-Factor.*

The energy balance-sheet for the transformer on this load, as derived from the table is as follows :—

Energy in watt-hours given to primary circuit.	Energy in watt-hours taken from secondary circuit.
11 × 148 = 1,628	11 × 0 = 0
5 × 768 = 3,840	5 × 600 = 3,000
4 × 911 = 3,644	4 × 750 = 3,000
3 × 1,668 = 5,004	3 × 500 = 4,500
1 × 4,720 = 4,720	1 × 4,500 = 4,500
Total = 18·836 B.T.U.	Total = 15·000 B.T.U.

Energy loss = difference = 3·836 units in 24 hours.
Iron all-day loss = 24 × 148 = 3·552 units.
Copper all-day loss = 0·284 ,,
Total loss = 3·836 ,,

All-day efficiency on this 10 per cent load-factor $= \frac{15{\cdot}000}{18{\cdot}836} = 74{\cdot}3$ per cent.

Table III.

C^2R losses in the primary cable on the assumption that four 6,000-watt transformers are placed at the end of one mile run of double primary cable, each single cable having a copper section equal to 7/16 and a total go and return resistance of 4 ohms.

Primary pressure at transformer terminals = 2,400 volts. Total volts lost on primary cable at full load = 40, or under 2 per cent. Load diagram as in Tables I. and II.

A.—Four 6,000-Watt "Hedgehog" Transformers.

Energy loss in cable in watt-hours.
11 × (1·194 × 4)² × 4 = 1,003
5 × (1·228 × 4)² × 4 = 482
4 × (1·270 × 4)² × 4 = 413
3 × (1·410 × 4)² × 4 = 381
1 × (2·436 × 4)² × 4 = 380
Total = 2·659 B.T.U.

B.—Four 6,000-Watt Mordey Transformers.

Energy loss in cable in watt-hours.
11 × (0·076 × 4)² × 4 = 41
5 × (0·323 × 4)² × 4 = 33
4 × (0·387 × 4)² × 4 = 38
3 × (0·692 × 4)² × 4 = 92
1 × (1·980 × 4)² × 4 = 250
Total = 0·454 B.T.U.

Hosted by Google

primary line, in the case of the four "Hedgehog" transformers, was 2·659 B.T.U., while in the case of the four closed-circuit transformers it was only 0·454 B.T.U.; the difference was therefore 2·205, and this was the difference which had to be supplied in order to reduce the losses in the line to the value which they would have with good closed-circuit transformers at the other end. There would also be a slight reduction in the case of the copper losses of the transformer, but as these together only amount to one-quarter of a unit in the 24 hours, they saw by a comparison of the figures that if the condenser dissipated 2·4 B.T.U., and the utmost amount that it could save on this 10 per cent. load diagram was something like 2·3 B.T.U., or rather less than 2·4 B.T.U., the addition of the condenser to the line was merely robbing Peter to pay Paul—it put on, on the whole, rather more than it took off from the energy balance-sheet—hence, although it was very easy to talk about adding condensers to save magnetising energy and copper losses in the line, unless an actual condenser could be produced which was absolutely free from dielectric hysteresis, it merely changed the place of the waste of energy. It was obvious that at less load-factors the condenser was a source of waste. It was perfectly clear, to his mind, that a condenser, therefore, did not necessarily effect the saving which Mr. Swinburne thought it did. Dr. Fleming then referred to Mr. Swinburne's criticism of his method of measuring the drop of the secondary volts, and of his explanation that the "Hedgehog" loss was due to eddy currents in the copper. There was one drastic remedy that Mr. Swinburne might apply without hesitation, and that was to return to the kind of "Hedgehog" transformer that was first devised by Mr. Cromwell Varley in 1856. Mr. Swinburne's "Hedgehog" transformer had its "Hedgehog" ends very little projecting beyond the coils. Mr. Varley made a transformer in 1856, in which he left the ends of the wires at both ends long enough to be folded back and joined together round the body of the transformer. By returning to Mr. Varley's type of transformer, and making a closed magnetic circuit, Mr. Swinburne would get rid at one blow of all his difficulties.

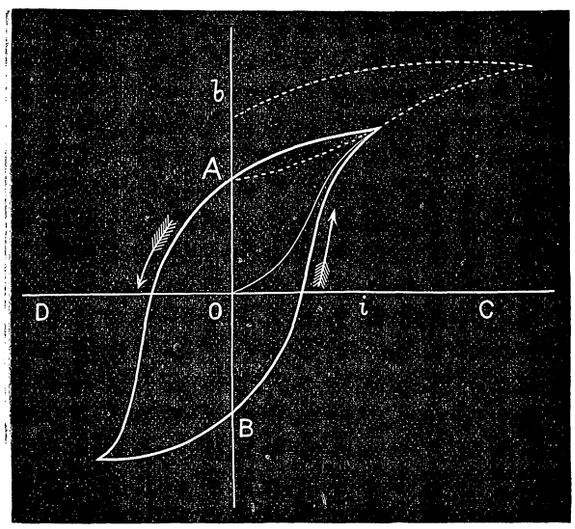

FIG. 1.

Coming to Prof. Forbes' remarks upon the importance of designing transformers especially for their work, he (Dr. Fleming) feared they had been too much urged to admire mere high efficiency at full load without regard to the nature of the work to be done. The advent of large schemes for power transmission would show the necessity of designing transformers specially with regard to their character of work, and of adopting probably a much lower frequency than was now employed in the majority of transformers used for electric lighting. In connection with the Westinghouse transformer, no one seemed to have called further attention to the fact which he had pointed out, that the core of the Westinghouse transformer tested by him was made of mild steel. He knew the great difficulties which manufacturers of transformers had to contend with in procuring identical qualities of iron on all occasions; and it seems to him that the only way out of that condition of things would be for some enterprising persons to turn their attention seriously to the production of electrolytic iron of definite chemical purity, and which could be made on the same manufacturing scale as electrolytic copper was at the present time. Referring to what Mr. Evershed had said in admiration of Prof. Ryan's work, yet that work left, said Dr. Fleming, many points still unsettled. The chief value of Prof. Ryan's work was in showing clearly the relative phases of the current and electromotive force in the actual working transformer, which, up to that time, had been entirely a matter of guesswork. It was, however, satisfactory to have touched the bottom at last, and to have established as a combined result of many workers' experiments, the fact that the iron losses in a transformer were, for all practical purposes, constant at all loads, and that the hysteresis losses were practically independent of the speed. Mr. Evershed concluded his remarks by expressing his regret that some of our live professors had not come in contact with a live transformer some years ago, and concludes by rejoicing over one who had done so at the eleventh hour. Perhaps it was only permissible to remind Mr. Evershed of the fact that the evolution of knowledge was to a large extent a matter of money. It often cost very little to propound a theory, it sometimes cost a good deal of money to arrive at a fact. It had become the fashion lately to cavil at the supposed tendency in scientific teachers to supply too much theory and too few facts. The manufacturers had the remedy largely in their own hands. Let them see that teachers who had the means and training to conduct experimental research were not starved in apparatus and the means of testing in practical work the theories they evolved. Some of the work of which Mr. Evershed had spoken in admiration was carried out by means of a complete alternator and transformer plant given by the Westinghouse Company to an American college. Could anyone point to an English college which had a similar gift made to it by an English firm? Moreover, they did not, however, find as a general rule that manufacturers were specially anxious to provide professors with results of experiments, by which alone they could test their theories. He was not saying that they ought to do so, because he was sufficiently in contact with practical work to know that manufacturers were not likely to give away the results of experiments, which may have cost them hundreds of pounds; but, at any rate, until they were prepared to do so, and to furnish their quota towards the progress of public information, it would, probably, only be bare justice for them to withhold destructive criticism on those who, at any rate, had furnished them freely with the best that they had at their disposal. Mr. Mordey had given the results of a number of exceedingly careful experiments, upon the sudden rush into transformers, which might occur at the moment of connecting them to the primary circuit.

He wished to correct a view which he put forward in the Paper that the rush into the transformer was an alternating rush. His present opinion was that the whole effect was over in less than one period. Without dogmatising at all on what might require further elucidation, the following suggestions had occurred to him as a possible explanation of the whole of the observed effects. If they considered a single magnetic cycle, which was being traversed in the direction of the arrows by the iron (Fig. 1), let them suppose that when the current finally ceased the magnetism left in the iron was represented by OA. When they closed the circuit and started the current again it must either begin to increase positively, that was towards OC, or negatively, that was towards OD. If the latter, the magnetic cycle was picked up at the point where it was left, and continued in the proper direction and the proper back electromotive force due

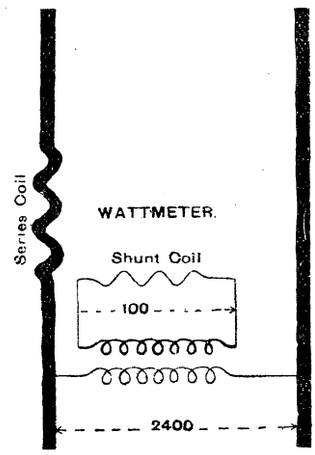

FIG. 2.

to rate of change of induction obtained at each instant. If, however, the current began again to increase positively, then the true permanent magnetic cycle was not picked up at once, but a loop shown by the dotted line was formed on the magnetic cycle curve. This loop started off at first nearly horizontally; in other words, the rate of change of induction with magnetising force, or $\frac{d\,B}{d\,i}$ was nearly or quite zero. Hence the back electromotive force of self-induction was nearly or quite zero, and there being nothing to keep back the current, it came in with a rush until the reversal of the electromotive force restored things to their normal state. If the current were broken slowly, so as to cause the magnetism of the iron to be entirely destroyed, then, on beginning again, they had to do as it were with virgin iron, and under those circumstances the value of the rate of change of induction with magnetising force, or $\frac{d\,B}{d\,i}$, was not zero. Hence there could be no very great rush.

Dr. Sumpner naturally put in a claim for his own method of testing transformers. As a matter of fact, it was not generally, outside a factory, most convenient to test transformers in pairs. He had recently modified his dynamometer method, and got rid of the large non-inductive resistance in the shunt coil, making use of a transformer instead to supply the current for the shunt coil of the wattmeter (*see* Fig. 2). For that purpose he placed a small tranformer across the primary mains, and connected the low-resistance shunt coil of the wattmeter through one incandescent lamp to the secondary terminals of the transformer. It was easily seen that since the secondary current in a transformer was in exact opposition as regards phase with the terminal primary electromotive force, this arrangement would give a current through the shunt coil of the wattmeter which was in synchronism with the primary impressed electromotive force. The arrangement did not involve nearly so much power expenditure as when non-inductive shunt resistances were employed as in the method described in the Paper. The really important point in Dr. Sumpner's speech was his investigation of the cause of error in the Swinburne wattmeter, and he

Hosted by Google

(Dr. Fleming) did not think it possible to resist the logic of Dr. Sumpner's experiments and conclusions.

He now came to Mr. Crompton's remarks and those which fell from Mr. Wright. Some of Mr. Crompton's conclusions could not be allowed to pass without challenge. In some respects Mr. Wright was even a more formidable opponent than Mr. Crompton, for, if anybody in this world understood the design of transformers, and what they would do, it was Mr. Arthur Wright; and since he had also had wide experience in the practical management of low-pressure stations, his endorsement of Mr. Crompton's contention, that there was no room for an alternating current station inside of a radius of a mile and a quarter, was one which, if allowed to pass unmet, would leave the impression that the matter was beyond dispute. However, so far from there being no room for an alternating current station inside a radius of a mile and a quarter, it was simply a matter of fact that a low pressure feeder of a mile long supplying on the usual load-factor, cost more to lay down and cost more to maintain than the high pressure transformer feeder of the same capacity. That was the proposition that he proposed to maintain. He would assume that the load diagram of the supply was 10 per cent., that was to say, that it was a supply of the following nature: eleven hours no supply, five hours one-tenth of full supply, four hours one-eighth of full supply, three hours quarter of full supply, and one hour three-quarters of full supply. This diagram was equal to 2½ hours at full load, or to a load factor of very nearly 10 per cent. No one could assert that this load factor was an exceptional one. Having assumed this, he proposed to demonstrate that if they took two feeders, each of 24 kilowatts maximum capacity and a mile long, one a low pressure three-wire feeder supplying at the business end at 200 volts across the outer mains, and the other a high pressure feeder worked at 2,000 volts at the dynamo and supplying a 24 kilowatt transformer at the business end to reduce to 100 volts, that the high pressure feeder would cost a less annual sum to maintain than the low pressure feeder. He should take it that the cost of the unit generated at the dynamo terminals was the same in both cases. First let them consider the three-wire feeder. He had taken three cases as to the drop of pressure in that feeder, and in Table IV. had calculated out the diurnal losses in the feeder on the 10 per cent. diagram on the assumption of a 40 per cent. drop, a 30 per cent. drop, and a 20 per cent. drop respectively, the full load current in each outer main being 120 amperes, and the sizes of the mains required to give these drops being calculated from the maximum current. In case A (40 per cent. drop) the feeder loss in the 24 hours was 8·28 B.T.U., and the feeder delivery in the 24 hours was 60 B.T.U., or an all-day efficiency of 87 per cent. In Table V. he calculated the diurnal losses in the high-pressure feeder consisting of a mile of double 7/16 cable and a 24-kilowatt transformer, and on the assumptions made, the diurnal loss was 9 B.T.U. in the cable and transformer, and the delivery 60 B.T.U., or an all-day efficiency of 87 per cent. In Table VI. he had calculated in the same way the high-pressure feeder efficiency on the assumption that the single transformer was replaced by two 12-kilowatt transformers, and they would see from the table that the total loss in the transformer and cable on the 10 per cent. load diagram was 8·049 B.T.U., or an all-day efficiency of 88 per cent. Accordingly, at the distance of one mile on this load diagram, a transformer feeder of the kind supposed was equivalent, as far as regards energy losses, to the low-pressure feeder and both of them might be taken to waste 8 units per day in delivering 60 units on the 10 per cent. load diagram. The next thing that remained to be done was to estimate the relative capital outlay on the two feeders, and to fix figures for depreciation and interest. In doing this, he had not relied on his own estimates, but he had gone to responsible people and asked them to furnish him with figures at which they would be prepared to carry out the work of laying the respective feeders. The specification for the high pressure feeders was as follows: The primary cable to be concentric, each conductor having a section equal to 7/16, the resistance of the go and return, namely, 2 miles, being 4 ohms. Vulcanised india rubber to be used as insulation, taped and braided cable to be drawn into a wrought iron pipe, provided with 20 draw-boxes—a pit at the business end for the transformer, which was to be a 24-kilowatt transformer with a loss on open circuit of 1·35 per cent., and a loss on full load of 3 per cent., which gave an efficiency of 86 per cent. at 1/10th full load, and 96 per cent. at full load. The estimate for that work complete, laid in the ground, but exclusive of the cost of opening and making good the road, was £465. For the low-pressure feeder the specification was as follows: Low pressure feeder to consist of three cables, each one mile in length, respectively 37/16, 19/15, and 37/16, giving a drop of 40 per cent., when 120 amperes were flowing, and when 200 volts were maintained at the business end between the outer cables. The cables to consist of Callender's bitumen lead-covered and steel-armoured cable, laid in the ground direct. Total cost of laying one mile of three-wire feeder exclusive of cost of opening and making good the road, £925. He had checked the figures and compared them with those-

Table IV.—*All-Day Efficiency of Three-Wire Feeder one mile long, giving a maximum supply of 24 kilowatts at 200 volts constant pressure at the business end.*

Let the diurnal load diagram be as above, viz.:—

11 hours no supply
5 „ 1-10th full load
4 „ 1-8th „ „
3 „ 1-4th „ „
1 „ 3-4th „ „
} = 10 per cent. load-factor.

Case A.—40 per cent. drop at full load. Full current = 120 amperes in each main; resistance of each outer main = 0·33 ohm; cables, 37/16, 19/15, 37/16.

Feeder Loss in Watt-Hours.	Feeder Delivery in Watt-Hours.
$11 \times 0 \times \frac{2}{3} = 0$	
$5 \times (12)^2 \times \frac{2}{3} = 480$	$5 \times 12 \times 200 = 12{,}000$
$4 \times (15)^2 \times \frac{2}{3} = 600$	$4 \times 15 \times 200 = 12{,}000$
$3 \times (30)^2 \times \frac{2}{3} = 1{,}800$	$3 \times 30 \times 200 = 18{,}000$
$1 \times (90)^2 \times \frac{2}{3} = 5{,}400$	$1 \times 90 \times 200 = 18{,}000$
Total = 8·28 B.T.U.	Total = 60·000 B.T.U.

$$\text{All-day efficiency} = \frac{60}{68{\cdot}28} = \text{per cent.}$$

Case B.—30 per cent. drop at full load. Full current = 120 amperes in each main; resistance of each outer main = 0·25 ohm; cables, 37/14, 19/14, 37/14.

Feeder loss in watt-hours.	Feeder delivery in watt-hours.
$11 \times 0 \times \frac{1}{2} = 0$	
$5 \times (12)^2 \times \frac{1}{2} = 360$	$5 \times 12 \times 200 = 12{,}000$
$4 \times (15)^2 \times \frac{1}{2} = 450$	$4 \times 15 \times 200 = 12{,}000$
$3 \times (30)^2 \times \frac{1}{2} = 1{,}350$	$3 \times 30 \times 200 = 18{,}000$
$1 \times (90)^2 \times \frac{1}{2} = 4{,}050$	$1 \times 90 \times 200 = 18{,}000$
Total = 6·310 B.T.U.	Total = 60·000 B.T.U.

$$\text{All-day efficiency} = \frac{60}{66{\cdot}31} = 90 \text{ per cent.}$$

Case C.—20 per cent. drop at full load. Resistance of each outer main = 0·165 ohm; cables, 37/13, 19/13, 37/13.

Feeder loss in watt-hours.	Feeder delivery in watt-hours.
$11 \times 0 \times \frac{1}{3} = 0$	
$5 \times (12)^2 \times \frac{1}{3} = 240$	$5 \times 12 \times 200 = 12{,}000$
$4 \times (15)^2 \times \frac{1}{3} = 300$	$4 \times 15 \times 200 = 12{,}000$
$3 \times (30)^2 \times \frac{1}{3} = 900$	$3 \times 30 \times 200 = 18{,}000$
$1 \times (90)^2 \times \frac{1}{3} = 2{,}700$	$1 \times 90 \times 200 = 18{,}000$
Total = 4·14 B.T.U.	Total = 60·000 B.T.U.

$$\text{All-day efficiency} = \frac{60}{64{\cdot}14} = 93 \text{ per cent.}$$

Table V.—*All-day efficiency of 24-kilowatt transformer on 10 per cent. load diagram, and losses in double 7/16 primary cable one mile long feeding the same.*

Let the transformer have 1·35 per cent. loss on open secondary circuit, and 1·35 + 1·60 per cent. loss at full load. This gives an open-circuit loss of 324 watts, and an efficiency of 86 per cent. at one-tenth full load, and 96 per cent. at full load.

The energy balance-sheet for the transformer on the above load diagram is:—

Energy in watt-hours given to primary circuit.	Energy in watt-hours taken from secondary circuit.
11 × 324 = 3,564	11 × 0 = 0
5 × 2,762 = 13,810	5 × 2,400 = 12,000
4 × 3,372 = 13,488	4 × 3,000 = 12,000
3 × 6,420 = 19,260	3 × 6,000 = 18,000
1 × 18,612 = 18,612	1 × 18,000 = 18,000
Total = 68·734 B.T.U.	Total = 60·000 B.T.U.

The primary cable losses ($C^2 R$) on same load in watt-hours are—

$11 \times 4 \times (\frac{1}{8})^2 =$	1
$5 \times 4 \times (1)^2 =$	20
$4 \times 4 \times (1\frac{1}{4})^2 =$	25
$3 \times 4 \times (2\frac{1}{2})^2 =$	75
$1 \times 4 \times (7\frac{1}{2})^2 =$	225
Total = 0·346 B.T.U.	

Total loss in 24 hours in cable and transformer = 8·734 + 0·346 = 9·08 B.T.U.

All-day efficiency = 87 per cent.

Table VI.—*All-Day Efficiency of Pair of 12-Kilowatt Transformers on a 10 per cent. Load Diagram, and also Energy Losses in a Double 7/16 Primary Cable one mile long feeding the same.*

The energy balance-sheet of the transformers (Ferranti), as taken from tables of observation, is as follows:—

Energy in watt-hours given to primary circuit.	Energy in watt-hours taken from secondary circuit.
11 × 2 × 149 = 3,278	11 × 2 × 0 = 0
5 × 2 × 1,189 = 11,890	5 × 2 × 1,055 = 10,350
4 × 2 × 1,580 = 12,640	4 × 2 × 1,422 = 11,376
3 × 2 × 3,064 = 18,384	3 × 2 × 2,903 = 17,418
1 × 2 × 8,932 = 17,864	1 × 2 × 8,614 = 17,228
Total = 64·056 B.T.U.	Total = 56·372 B.T.U.

The primary cable losses ($C^2 R$) on the same load in watt-hours are—

$11 \times (0{\cdot}076 \times 2)^2 \times 4 =$	1
$5 \times (0{\cdot}503 \times 2)^2 \times 4 =$	20
$4 \times (0{\cdot}675 \times 2)^2 \times 4 =$	29
$3 \times (1{\cdot}265 \times 2)^2 \times 4 =$	77
$1 \times (3{\cdot}713 \times 2)^2 \times 4 =$	237
Total = 0·364 B.T.U.	

Total loss in 24 hours in cable and transformers = 7·684 + 0·364 = 8·048 B.T.U.

All-day efficiency = 88 per cent.

Hosted by Google

of a number of other makes of cables and transformers. He would, therefore, take it as a perfectly certain fact that the cost of the low-pressure feeder, apart from the opening and making good of the ground, would cost £1,000 per mile; that the transformer feeder would cost not far from £500, £400 for cable and £100 for transformer and pit. They then had to compare the annual expenditure on the two feeders respectively; assuming that the 10 per cent. diagram represented the every-day diagram throughout the year. Since the loss on both cases was the same, namely, 8 units per diem; if they took the manufacturing cost of the unit as 3d., it would give a total annual cost for power wasted in the two cases of £36. 10s. To this must be added 5 per cent. on the capital outlay for interest, which, taking the capital outlay on the low-pressure feeder as £1,000, and the capital outlay on the transformer feeder as £500, amounting respectively to £50 and £25. The next question was the depreciation to be placed respectively against the several items. Here they would find great differences of opinion. He would take the depreciation on the transformer at 15 per cent., at which he knew many makers of transformers would exclaim, as putting the transformer on an equality with a secondary battery. Placing, then, the cost of the transformer at £100, this amounted to £15. On the high-pressure cable he would take a depreciation of 5 per cent. on £400, making £20 per annum. On the low-pressure cable he would take the depreciation at the exceedingly moderate amount of 2½ per cent. No doubt manufacturers of high-pressure cables would consider that he was doing them an injustice, but he wished to put his case first in a manner which would render it impossible for the supporters of low pressure to refute it. They then had the following comparative annual costs :—

	Low-pressure feeder.	High-pressure feeder.
Annual cost of energy wasted in both cases at 3d. per unit	£36 10 0	£36 10 0
Interest on capital outlay at 5 per cent	50 0 0	25 0 0
Depreciation, 2½ per cent. on the low-pressure feeder	25 0 0	— — —
Five per cent. on the high-pressure feeder	— — —	20 0 0
Fifteen per cent. on transformer	— — —	15 0 0
Total	£111 10 0	£96 10 0

As long as they kept within the limits of practical experience, they would find it to be demonstrated without possibility of refutation, that the annual cost of the high-pressure feeder of one mile in length, delivering 24 kilowatts as a maxium load, was considerably less than the annual cost of maintenance of the low-pressure feeder, and in particular, that the capital outlay for the low pressure feeder was about double that of the high-pressure feeder. Taking lower percentage voltage drops the case became decidedly favourable to high-pressure. The figures, which he had endeavoured in every way to subject to test, did not in the least degree confirm the statements of Mr. Wright and Mr. Crompton, that there was no room inside a radius of a mile and a quarter for an alternating current station; on the other hand, they showed most decidedly that there was no room outside a radius of one mile for a continuous current station. His firm conclusion was that the economical radius of supply by three wire direct current systems was reached at distances when the feeders had an average length of somewhat less than one mile with load diagrams of 10 per cent. The case became much more unfavourable to the low pressure supply, if they supposed the load diagram to improve, they did not build stations with the object or hope of remaining permanently with load factors of 10 per cent. No one was making greater efforts than Mr. Crompton to increase those abnormally low load-factors. The result of improving the load-factor must, therefore, be to diminish the efficiency of the low-pressure feeder. This was clearly obvious, because, if the load-factor rose to 100 per cent., the efficiency of the feeder with the 40 per cent. drop would only become something like 70 per cent., and this was the limit towards which the efficiency or distribution of the low-pressure system tended, as the load-factors were progressively increased when secondary batteries were not used. Who was to say what it fell to when secondary batteries (whatever their additional advantages) were employed? On the other hand, it was a matter of simple demonstration that, in proportion as the load-factors increased, the efficiency of distribution of the high-pressure feeder must tend as a limit towards 95 per cent.—2 per cent. being the drop in the line, and 3 per cent. the loss in the transformer. In all the above he had altogether left out of account the capital outlay on the generating plant. To supply a maximum of 100 kilowatts at the business end of a high-pressure feeder they had only to put down a generating plant capable of supplying, at the maximum, 105 kilowatts at the dynamo end, because the losses at full load were only 5 per cent.; but if, with a low-pressure feeder to do the same work, they had to put down generating plant with a capacity of 140 kilowatts as its maximum output, because the maximum waste of 40 per cent. occurred in the low-pressure feeder at the very hour of maximum demand at the business end. That, of course, very seriously affected not only the whole capital outlay in generating plant, but the whole annual cost of the system and opened up a view of the case which must not be lost sight of in considering all these questions. In fact, the enthusiastic advocates of low-pressure working had done their utmost to draw the attention of the world to the losses occurring in transformers, but they had judiciously kept exceedingly silent on the equally important matter of the losses in low-pressure feeders. With regard to Prof. Kennedy's interesting remarks, it was impossible to deny that the system of house transformers was one in which the all-day losses were exceedingly large, butnone of them who at any time advocated alternating current systems had ever looked upon that house-to-house system as anything more than necessary in initial stages of supply. Where the alternating current stations had been, or were being, laid out with knowledge and skill and experience from the beginning, nothing but a system of transformer feeders and low-pressure secondary networks was being adopted, and when they came to collate the results of sufficient experience of the working of that system with the results of working of low-pressure systems there was no reason to believe that the balance of advantage would be found on the side of the continuous current system. There was one other point, and that was that even when they were dealing with the same percentage load-factor, there might be a great difference between the efficiency of distribution by a feeder when the diagram-form altered in shape, even if it still included the same area. Let them consider a load-diagram of the following kind :—Nine hours at no load, eight hours at one-eighth of full load, three hours at one-fourth of full load, two hours at one-half of full load, and two hours at three-fourths of full load. That was equivalent in area to 4¼ hours at full load or to an 18 per cent. load-factor. If they took the low-pressure three-wire feeder in the case A, and calculated the feeder loss and feeder delivery in 24 hours, they would find them to be 18·6 units and 102 units respectively on this 18 per cent. diagram, or a feeder efficiency of 84·5 per cent. If, however, they took the same percentage load-factor and considered it as made up by 4¼ hours at full load and 19¾ hours at no load then, on calculating the feeder loss and feeder delivery they would find them to be 40·8 units and 102 units. Hence with the same percentage load-factor the efficiency of distribution had fallen to 70 per cent. On the contrary a transformer feeder would have benefited in efficiency by the concentration of the load. One of the most remarkable qualities of a low-pressure feeder was the degree to which a very moderate duration of full load depressed the efficiency of distribution. If, however, they considered the alternating current feeder the above facts were conversely illustrated. The higher or more concentrated the load-factor the better the efficiency of distribution.

Lord Bacon said that "truth emerges more easily from error than from confusion," and if the outcome of his work and the discussion which had taken place on it was in any degree helpful in furthering their knowledge of the subject of transformer working, and dispelling illusions or confusions with which it might be surrounded it would not prove a disadvantage for them to have so fully discussed the Paper they had done him the honour to receive.

THE BRISTOL LAMPS AND BATTERIES.

Some time ago the London General Omnibus Company decided to try the experiment of introducing electric lamps into the leading routes of omnibuses owned by them, and, after negotiations, entered into an arrangement with the Bristol Electric Safety Lamp Works to supply 140 omnibuses with small incandescent lamps worked by their patent battery. Fig. 1 shows lamp and battery and contact plates, and Fig. 2 shows the interior of an omnibus and the position of the battery and lamp with connections.

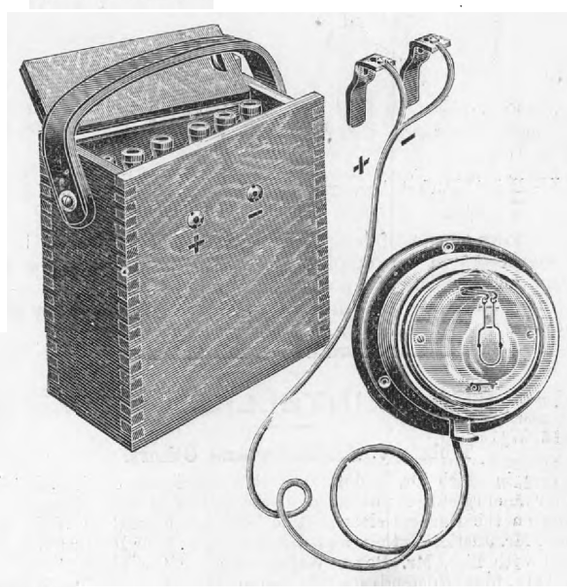

FIG. 1.—The Bristol Lamp and Battery.

The battery selected for this service weighs about 8lb., and is placed as shown in a wooden box under one of the seats. The box is provided with two brass spring terminals, which make automatic contact with the battery when it is let down into the box. The lamp is of a special design, and is made as shallow as possible, to allow of its being placed in the centre of the roof, it being found that this arrangement distributes the light most satisfactorily all over the carriage. The lamp design is covered by Mr. L. Bristöl's patents, and offers great advantages for omnibus work, since breakage of filaments from the shaking of the carriages is avoided. Ordinary bottom loop lamps are used, and two wire hooks, which expand sideways, clasp these loops firmly. A wire spring, which catches the top of the incandescent lamp, forces it against the wire hooks and increases the clutch of the hooks.

Hosted by Google

The batteries are charged at Victoria, seven in series, from the Westminster Electric Supply Corporation's mains, small incandescent lamps being used as resistances. The batteries have, we understand, stood the test in a very satisfactory way, and the severe shaking to which they are necessarily subjected while in use has had no effect upon the plates.

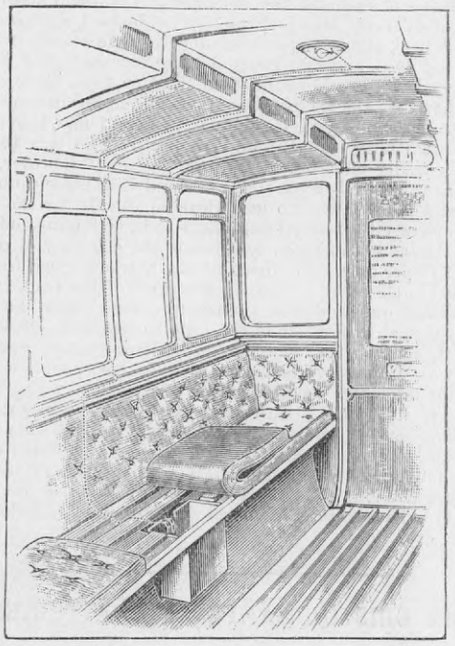

FIG. 2.—Interior of Omnibus, showing Lamp, Battery and Connections.

The installation has been very successful, the only difficulty experienced being to get time enough to charge the batteries for the whole night's run, as the lamps are delivered between the hours of 9 and 12 a.m., and the serving out commences about half-past 2, but a sufficient number of spare batteries now provided will overcome this difficulty.

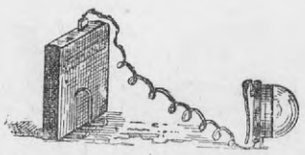

FIG. 3.—Bristöl Pocket Accumulator and Button-hole Reading Lamp.

Fig. 3 shows a type of lamp and battery which is used by the ticket inspectors in the employ of the London General Omnibus Company, and consists of a pocket accumulator and a button-hole lamp. This lamp has been in use for the past year, and has given satisfaction.

LEGAL INTELLIGENCE.

Tibbits v. Alabaster and Others.

This case, in which Dr. Tibbits sues the proprietors of the *Electrical Review* for an alleged libel published in the course of some comments on his report on the Harness electropathic belt, was opened on Wednesday last before Mr. Justice Mathew and a special jury. Sir Richard Webster, Q.C., and with him, Mr. Roger Wallace, was for the plaintiff, and Mr. Walton, Q.C., for the defendants. In opening the case Sir Richard Webster read the alleged libel, which attributed ignorance of electrical laws to the plaintiff, and suggested that the report he made on Harness's belts called for action on the part of the medical authorities. The plaintiff gave evidence to the effect that the report was an honest one, made after a careful testing of the belts, and said that they would generate electricity. A number of scientific and medical witnesses, who had also tested the belts, expressed the view that the belts generated electricity, and that the current would pass through the body of the wearer. All the witnesses in cross-examination admitted that if the two poles of the belts were not coupled, there would be no current. At this stage the Court adjourned until Thursday.

On Thursday morning Mr. Walton, Q.C., opened the case for the defendants, and called evidence, both electrical and medical, including Lord Kelvin, to show that the belts when unconnected would not produce a current, and that when connected the current was so small as to be almost inappreciable. In summing up the case for the defendants, Mr. Walton held that the article was a fair comment, and that his evidence had shown that competent men drew from the pamphlet the inference that the writer knew little of electricity. He appealed to the jury not to give Mr. Harness, who put Dr. Tibbits forward, an advertisement by their verdict. The Court then adjourned until to-day. A fuller report of these proceedings will appear in our next issue.

AMERICAN NOTES.

(FROM OUR OWN CORRESPONDENT.)

NEW YORK, *Feb.* 3, 1893.

The Incandescent Lamp Question.—The electric lamp situation continues to be the absorbing topic in electrical circles. In conformance with the ruling of the Court, as announced in a previous letter, both the complainants and the defendants in the suit of the General Electric Company *v.* The Beacon Vacuum Pump and Electric Company, presented on Wednesday last their printed arguments. In addition to this the defence asked leave to introduce new evidence. Mr. Fish, counsel for the plaintiff company, appeared to oppose the introduction of this new evidence, and the question was argued in Chambers before Judge Colt. The result of this argument was that the judge decided to admit the new evidence presented, which seems to be another point gained by the defence. On the part of the latter the chief additional evidence was another exhibit of a Goebel lamp, which has platinum leading-in wires. Additional affidavits were also presented on both sides, and the case, as now in hand, has been taken into consideration. The Westinghouse Company seems to be the only organisation in this country who will not be affected in one way or another whatever the outcome of this present suit. They claim that their new separable lamp leaves them really master of the situation, and profess to be entirely unconcerned as to the result. The feeling among the outside manufacturers, who are accused of infringing the Edison patents, seems to be one of growing confidence; while they will not say that they expect an injunction will be denied in this action, still they feel that every moment of time gained strengthens their side of the case and think that they will be able eventually to procure evidence sufficiently strong to enable them to continue the manufacture of lamps.

Referring again to the lamp situation, the Chicago Edison Company, the local licensee for the sale of Edison lamps, having declined to sell lamps to parties not using the General Electric Company's machinery, the National Electric Construction Company brought the matter to the notice of the Courts that it had been unable to procure lamps for its circuits. The trial consumed the greater portion of last week, and resulted in the judge ruling that the Chicago Edison Company, as the agent of the General Electric Company, would be obliged to furnish the National Electric Construction Company with all the lamps necessary to supply its customers, and at a price not to exceed 42 cents. per lamp. This is the only relief thus far granted to outside companies against what now appears to be the declared policy of the General Electric Company of closing up all competitors, or forcing them to use their machinery. But since the General Electric Company are unable to supply the whole demand for lamps, it will be seen that this relief will be totally inadequate if the policy is continued to the end.

The Green Trolley Patent.—Another feature in the electrical field has been brought into prominence during the past week by the reported sale of the Green trolley patents to the General Electric Company. It seems that Geo. F. Green, of Kalamazoo, Michigan, received two patents, Nos. 465,407 and 465,432, on December 15, 1891, which are claimed to be fundamental, covering the use of the trolley for electric street car propulsion. These patents were originally filed September 15, 1879; being somewhat indefinitely stated, it appears possible to interpret them as covering the whole field. The application as originally filed was promptly rejected, such action being taken on September 20, 1879. In August, 1881, a substitute set of drawings, including five new figures, were filed, but these new features were afterwards struck out. Again substitute specifications

Hosted by Google

and drawings were filed, and after various amendments had been insisted upon, the Patent Office wrote to Green as follows: "The amendment filed January 2, 1882, overcomes the objections urged, but future action in the case will be suspended until after the determination of a pending interference involving the invention claimed by an applicant, when a new interference will be declared between this application and that of the successful party." As a result of this suspension of his case, Green's application lay dormant in the Patent Office until the spring of 1885, when the interference referred to in the letter, between Stephen D. Field, E. Werner Siemens, and Thomas A. Edison was decided in favour of the first-named. Meanwhile, other applications besides Green's were waiting to be put in interference with the successful party, and when Field, unable to get his patent, in spite of his victory over Siemens and Edison, petitioned the Commissioner that the Examiner be directed to send his application to issue, the Chief Examiner entertained the petition with permission to Green and the other interested parties to be heard. On this occasion Green formally requested that Field's patent be denied, and after much interchange of letters between the Patent Office and the applicant, the latter had remodelled his claims very materially. Green's attorneys then carried his case to the Supreme Court of the District of Columbia, where a decision was given in favour of the majority of Green's claims, and the Patent Office was forced to pass the case and to issue the patents, as it did in December, 1891. Should the patents of Green be upheld by the Courts of Last Resort, the General Electric Company will be in the same position in regard to electric railways employing the trolley as it is now *de jure* in regard to the incandescent lamp. What with the incandescent lamp litigation and that which may result from the Green patents, and from the claims of Dr. Wellington Adams, of St. Louis, who claims fundamental patents on the suspension of motors beneath the car body, the electrical industry is certainly in an unfortunate situation in this country.

CORRESPONDENCE.

MR. JUSTICE KEKEWICH'S JUDGMENT.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: In the Author's preface in chapter lxiii. of "Tristram Shandy," there occurs the following:—

"But in answer to this, Didius, the great . . . lawyer, doth maintain, and make fully appear that an illustration is no argument; nor do I maintain the wiping of a looking-glass clean to be a syllogism; but you all, may it please your worships, see the better for it; so that the main good these things do, is only to clarify the understanding previous to the application of the argument itself, in order to free it from any little motes, or specks of opacular matter, which if left swimming therein might hinder a conception and spoil all."

There was once upon a time a common, a real common, with public rights of way, and pasturage, etc., for the common advantage of the whole community, and no two individual commoners could in any way pretend to apply any principle "on the basis of their being absolute owners" of it.

Among the more important of the animals recently introduced and nurtured for its profit by this community, there were two, which while differing widely in all other qualities and adjuncts, had this in common, that they were both graminivorous—one of these was a sort of cart horse, but bigger; the other was a sort of carrier-pigeon, but much smaller. Now the pigeons being delicate fastidious little beasts, it was soon noticed that their stomachs were upset by the cart horses, who were decidedly coarse feeders; and besides they sometimes got "the jumps" from fright at seeing the cart horses so close. So the pigeon farmers said to the carters, "Go and take your big brutes away, they are spoiling the grass for our pigeons."

"Why no," said the carters, "we have as much right to the common as you have, and it is not only our big cart horses which they complain of, but that herd of bright bays; and even eating the same grass with their own bigger cousins, the real carrier pigeons, seems to disagree with them. It is you who should keep *them* to *themselves*; and besides our cart horses at most stray a little way on either side of our beaten tracks." "Your beaten tracks," screamed the little pigeons, "we have as much right to the roads as you have."

"Why, no," said the carters, "the roads are for traffic and draught, which we do; that is their *raison d'être*, and if you find the noises disturb your nerves it is not a hardship to you to avoid them; but if you must come, provide perches where wanted, which will keep you quite secure." "Perches be hanged!" said the carriers, "we will force you to fence your big brutes in, and then only we shall feel secure."

"Be reasonable," said the carters, "the little bit of the common you want for yourselves is one billion times less* than what we should have to fence, and even if we did, the complication of gates and drawbridges would so greatly interfere with our doing the cartage for the community as to practically stop it."

But the pigeon farmers would not listen to reason.—Yours, &c., FRANK WYNNE.

13, Ashley Gardens, S.W., Feb. 14, 1893.

A METHOD OF MEASURING DYNAMO EFFICIENCY.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: The following method of testing the efficiency of dynamos I venture to send to you, as, from its simplicity, it may prove of use where other methods are not applicable.

The electrical power produced is found in the usual way by the formula E C. To find the mechanical power supplied the formula $\frac{1}{2} I 4 \pi^2 n^2$ is made use of where I = moment of inertia of the armature V N = revolutions per minute. If the driving power be suddenly cut off whilst the dynamo is running the rate at which the speed begins to diminish will be some function of the power the dynamo was absorbing. The dynamo is therefore run at a maximum speed, and the ratio at which speed diminishes is ascertained (by a speed counter and timepiece) for different velocities of rotation. A curve may be then plotted, showing the relation of rate of change of speed for any given speed. Hence $4 \pi^2 I n \times$ (rate of change of speed) will measure the power absorbed by the dynamo at speed "n."

It remains to find the moment of inertia of the armature. It will probably be impossible to get this by calculation, but it may be found by experiment. A disc flywheel may be attached to the armature, and the rate of loss of speed (when the power is cut off) compared with that of armature without flywheel. If the moment of inertia of the flywheel is known, then that of the armature may be calculated.

Variations of this method might be used to find the separate losses of power occurring in the various parts of the dynamo, if a current to excite the field-magnets or armature separately were available.

To obtain, however, the commercial efficiency of a dynamo by the above method, good time and speed measurers are the only requisites.—Yours, &c., J. R. A.

February 8, 1893.

[The experiment described by our correspondent is interesting, but it can hardly be relied upon for measuring the efficiency of a dynamo.—ED. *E.*]

"THAT BLESSED WORD, 'INSTALLATION'"!

TO THE EDITOR OF THE ELECTRICIAN.

SIR: You struck a sympathetic chord in my heart lately, and I wish you every success in your crusade against that "affected and pompous term." I have not used it for years. A householder *puts in* gas, or *lays on* water, or *fits* electric bells, or *runs* telephone wires, and *fixes* instruments; but when

* Professor P. G. Tait has calculated that the current which works the telephone is about a thousand million times less than the current used in ordinary telegraphic work.—FLEEMING JENKIN.

Hosted by Google

it comes to lighting the place he chokes himself! Can you help me to put down "accumulators"? I mean the word—not the cells themselves.—Yours, &c., W. H. MASSEY.

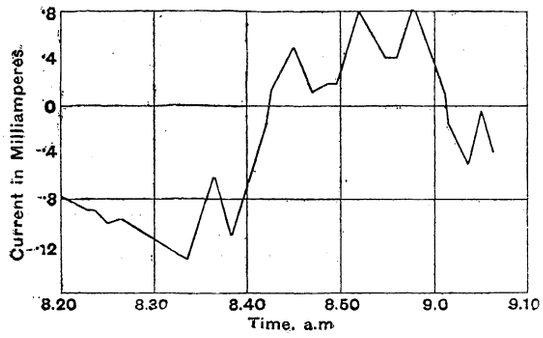
Twyford, R.S.O., Berks, February 12, 1893.

EARTH CURRENT DISTURBANCE.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: On the morning of the 5th inst., I observed on the Java-Australian cables an earth current disturbance, the nature of which may be seen from the accompanying diagram. Though the disturbance, as observed here, is not great, it may, however, be of interest when compared with particulars from other localities, should the disturbance have extended over a considerable area, as in the case of the two last magnetic storms recorded by you.

In testing by direct deflection the insulation resistance of one of the cables, I had what is probably a unique experience in cable insulation testing. The battery, consisting of 10 Higgins cells, was well insulated. The deflection was so unsteady with zinc current to line as to render the test worthless; with the copper current to line the deflection was still more unsteady, and after the current had been on for four minutes it was overcome by a current from the cable



Earth Current Disturbance observed on the Java-Australian Cables during morning, December 5, 1892. The Current is considered Positive or Negative as the Direction is Incoming or Outgoing with reference to this Station; and based on the Direction of a Positive Current from Battery through the Galvanometer. C.R. of Cable = 12,300 ω.

which gave a large deflection on the other side of zero. I then had the distant end of the cable earthed and observed the earth current for some time. The greatest strength of earth current observed coincides with that obtained here during the disturbances of May and July, and is from five to six times the normal earth current at that hour. I am unable to say how long the disturbance continued, as, the cable being required for other purposes, observations came to an end. One point I have noticed in these disturbances may have been observed by some of your readers, viz., that the rise and fall of current strength partake of the nature of a succession of impulses of variable period, occupying in this case about five minutes on an average.—Yours, &c.,

J. KENNEDY GIBSON.

Eastern Extension Telegraph Company,
Port Darwin, South Australia, December 14, 1892.

USEFUL FORMULÆ.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: The following rules are easy to remember and apply:—

(1.) To reduce centimetres to inches:—Multiply by ·4, and *deduct* 1in. in 5ft. from the result.

Note.—This rule gives 999·047in. in place of 1,000in.: *i.e.*, the error is 1in. in 1,000in., or in 83⅓ft., or in 28 yards, *in defect*: therefore, *add* 1in. in 1,000in.

(2.) To reduce metres to yards:—Add one-tenth; deduct one-tenth (*i.e.*, of the correction); add one-third (*i.e.*, of the last correction.)

Note.—This rule gives an error of 1·06 yards in 4,000 yards, *in defect*: therefore, *add* 1 yard in 4,000 yards.

(3.) To reduce kilometres to miles:—Multiply by ·6, and *add* 1 mile in 30 miles to the result.

Note.—This rule gives an error of 2·215 miles in 1,000 miles, *in defect*: therefore, *add* 2 miles in 1,000 miles.—Yours, &c., J. W. SHARPE.

Woodroffe, Bournemouth, February 11, 1893.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: The following is a simple rule for ascertaining velocities in miles per hour:—

Take any convenient distance in yards, and take the time required to traverse that distance in seconds.

Then $\frac{\text{yards} \times 2}{\text{seconds}}$ = miles per hour nearly.

To be more exact add $\frac{1}{40}$

Thus, 440 yards traversed in 15 seconds

$= \frac{440 \times 2}{15} =$ 58·66 miles per hour.

add $\frac{1}{40}$ 1·46

60·12 the true value being 60.

Again, say 20 yards traversed in 5 seconds;

then $\frac{20 \times 2}{5} = 8$ miles per hour approximately.

In most cases it is unnecessary to add the one-fortieth, because the error of observation would probably exceed that amount.—Yours, &c., HENRY LEA.

38, Bennett's-hill, Birmingham,
February 10, 1893.

TO THE EDITOR OF THE ELECTRICIAN.

SIR,—I hasten to make a correction in my letter of the 8th. For "sectional area in inches" please read "diameter (in inches) squared." So that the weight of water (in pounds) contained in one yard run of any pipe may be represented roughly by the diameter (in inches) squared, or, more accurately, by the diameter squared × 1·02.—Yours, &c.,

N. G. THOMPSON.

PRICE OF ELECTRIC SUPPLY.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: I hasten to point out that owing apparently to the awkward composition of the circular I sent you, you have fallen into a rather serious error by assuming that the basis of the reduction is on the number of lamps fixed, whereas the reduced charge comes in after *the maximum number of lamps used at one time* have been burning for two hours.

The distinction between this and the circular, as you understood it, will be obvious when you consider the case of private houses and hotels.

I agree with you that any consumer who uses the light between sunset and 8 p.m. only, will not derive any benefit from the reduction. These, however, are the most expensive customers to supply.

Your remark that the St. James' and Pall Mall Companies' revenue per lamp was 13s. 11d., evidently applies to the number of lamps fixed.

We find that about 22 per cent. of our clients will be benefited, more or less, by the reduced charge.—Yours, &c.,

ARTHUR WRIGHT.

TRADE NOTES AND NOTICES.

[*Notices for insertion under the above heading must reach the Office not later than first post Thursday morning. New Catalogues, Price Lists, and similar matter should be sent early in the week.*]

Our readers are reminded that the 1893 Edition of "THE ELECTRICIAN" Electrical Trades' Directory and Handbook is NOW READY. This useful book contains over 1,000 pages, and several new and handy features have been added. The price of the Directory and Handbook is 7s. 6d. Postage in the United Kingdom, 9d.; abroad, 1s. 4d.

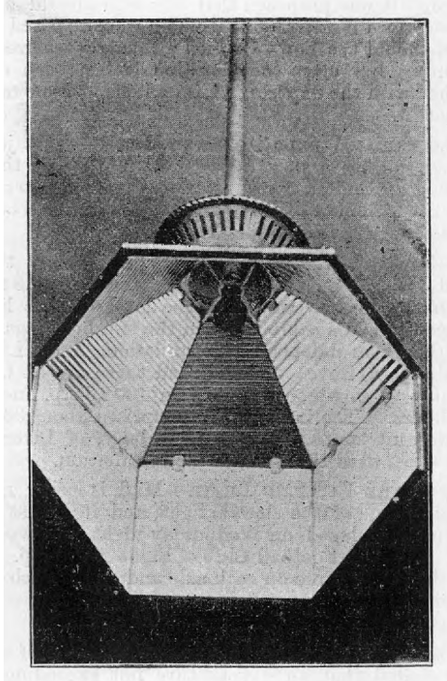
TENDERS ACCEPTED.—The tender of Messrs. J. Allen and Son has been accepted for the ornamental cast-iron electric light lamp-posts for the Promenade at Blackpool, subject to a sample post being approved by a Lighting Committee of the Town Council.

SALE BY AUCTION.—Messrs. Wheatley Kirk, Price, and Goulty announce in our advertisement columns that they will sell by auction, early in March, the entire contents of the Plashet Hall Works, Forest Gate, E., comprising six electric motor tram cars, dynamos, engines, machine tools, electrical fittings, &c.

APPOINTMENT.—Mr. T. P. Wilmshurst, electrician-in-charge of the Exeter Electric Light Company (Limited), has been appointed electrical engineer to the Halifax Corporation.

PRESENTATION.—Mr. James Brown, general foreman in connection with Messrs. Julius Sax and Co.'s electric installation at the Smithfield Markets, has been presented by the men working under him with a chronograph watch bearing a suitable inscription.

MESSRS. J. F. CLARKE AND SONS (MOORGATE-STREET, E.C.).—This firm have recently manufactured for Messrs. Julius Sax and Co. (who have the contract for the electric lighting of the Smithfield Markets for the Corporation of London) a number



of lamps and fittings from special designs for use in lighting the market shops and avenues. Messrs. Sax and Co. are joint owners with Messrs. Clarke and Sons of these registered designs, of which the latter are the sole manufacturers. The lamps are provided with fluted glass reflectors. The illustration shows the interior view of one of the designs used for shop lighting, which have proved eminently satisfactory. We understand that in order to give a mellow tint to the light, the reflectors are in some cases gilded instead of silvered.

MESSRS. A. MACLEOD AND COMPANY.—This firm have recently supplied the fittings for the extensive installation of the electric light of Messrs. Hunter and Company's large premises at Well Gate, Dundee, the installation includes both arcs and incandescents. The same firm have secured the contract for the electric lighting of Altyre House, Forres, the residence of Sir W. Gordon Cumming, Bart.

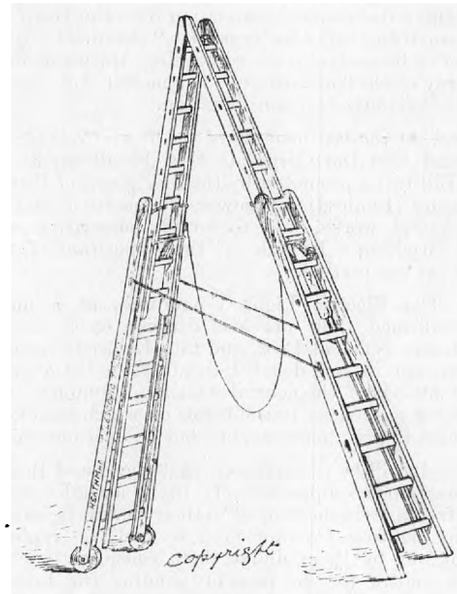
MESSRS. CAMPE AND CO. (SEYDELSTRASSE, BERLIN).—This firm send us a copy of their new catalogue in parallel columns of French and English text. The thirty-six large folio pages contain an extensive variety of globes and shades for the electric light, and many of the designs are very choice. The list includes a number of protector shades and lampscreen globes in various designs, as well as a large number of white iron and brass reflectors and shade holders. The catalogue is chiefly devoted to illustrations of globes, shades, and reflectors for incandescent lighting, but there are also several handsome designs in arc lamp globes.

MICANITE.—The Mica Insulator Company of New York send us a copy of their new price list of micanite plates, commutator segments, rings, washers, tubes, troughs, cloth, and paint, which they claim is used as an insulator by many of the largest electrical machinery manufacturers in the United States. This material consists of mica with lapped joints cemented together under pressure.

CROMPTON AND CO.'S DYNAMO AND MOTOR PRICE LIST.—We have received a price list containing prices of dynamos and motors made by Messrs. Crompton and Co., together with descriptions of their construction, diagrams showing general dimensions, notes on the selection of dynamos, particulars required when ordering dynamos or motors, information on steam consumption and direct driven dynamos coupled to high-speed engines. Full price lists are given, together with prices of sundries and a telegraph code. The illustrations and printing are excellent, but the best part of the list is the useful information and data.

"GOEHRING."—We have received from Messrs. J. M. Bennett and Sons, of Manchester, a very elaborate and finely-illustrated catalogue, relating chiefly to wooden mouldings cut by machinery. The feature of this material (which is pronounced "gearing") is the sinuous and interlacing of the mouldings, thus giving a large variety of waved and diaper patterns. Casing for electric wiring is made with ornamental covers. This waved moulding presents a variety of complicated patterns when mitred, and should be very useful for decorations in hotels, &c.

HEATHMAN'S LADDERS.—Messrs. J. H. Heathman, of Endell-street, London, W.C., send in some illustrated particulars of their telescopic adjustable ladders, suitable for use in cleaning and



attending to public lamps. The advantage of these ladders is, that although only 10ft. high when closed, they can be extended to 18ft. and can be stopped at any intermediate height. They are mounted on a pair of rubber tyre wheels, so that one man can readily move them about and use them. Several leading companies have them in use for trimming public and private lamps.

EDISON-SWAN COMPANY.—This Company have just issued their catalogue, Section IV., being a price-list of wires, cables, casings, and electrical sundries, the frontispiece to which is a bird's eye view of the extensive works at Ponder's End. The list comprises tables of the various descriptions of Ediswan electric light wires and cables.

GÜNTHER TURBINES.—Mr. W. Günther, of the Central Engineering Works, Oldham, forwards us a copy of his new illustrated catalogue and price list of turbines and general hydraulic machinery manufactured by him. The catalogue is prefaced by very full

Hosted by Google

descriptions of the "Jonval" and "Girard" turbine systems, and the illustrations accompanying the particulars given include views of the turbines for high, low, and medium falls. A section is also devoted to a description of the Pelton wheels with Mr. Günther's improvements. At a time when enquiries are frequent respecting the use of water power for electric lighting the information upon this subject, given in the catalogue, will be read with interest. A list of nearly 120 turbine installations for a large variety of commercial purposes is given.

TOOL-MAKING MACHINERY.—Mr. H. F. L. Orcutt sends us advanced sheets of machine tool lists of presses, drilling, planing, and grinding machines, manufactured by Messrs. Loewe and Co., of Berlin, for whom Mr. Orcutt is agent in this country. The lists are very fully illustrated, and include measurements and weights of the various machines described.

SCREWS, TERMINALS AND CONNECTIONS.—The Automatic Standard Screw Company (Limited) forward us samples of screws, terminals and connections, for the manufacture of which they possess patent machinery capable of executing orders of any magnitude in this special branch of trade. The samples sent show excellent workmanship and finish, and engineers will be well advised in asking for prices from the Company when requiring supplies. Among the samples are brass binding screws with screwed shanks of steel.

ENGRAVING BY ELECTRICITY.—A paragraph is going the round of the papers with reference to a process which is described as likely to seriously interfere with working engravers. There is nothing new in the process, particulars of which will be found on page 305 of *The Electrician* for July 25, 1890.

ELECTRIC ORGANS.—At a cost of £1,370 the Liverpool School for the Blind have ordered from the Hope-Jones Electric Organ Company a new four-manual organ, to contain 35 speaking stops, 2,024 pipes, and 22 coupling movements. Messrs. Jardine, of Manchester, have the contract for the construction of the instrument.

BELFAST.—The Police Committee of the Corporation have decided to light the new Chief Fire Brigade Station by electricity, and the work has been entrusted to Mr. Greenhill.

BOURNEMOUTH.—The Bournemouth and District Electric Supply Company (Limited) are asking permission from the Town Council to substitute a small number of underground "chambers" in lieu of the large number of boxes now used containing apparatus for controlling the supply of electric current. The matter has been referred to the Roads Committee for consideration.

BRIGHTON.—At the last meeting of the Town Council, Alderman Reeves moved that the Corporate Seal be affixed to a petition against the Bill being promoted by the Brighton and Hove Electric Light Company (Limited) for powers to construct and maintain electric lines and works, and to supply electricity within the Borough of Brighton. In spite of the opposition of Councillor Dell the motion was carried.

BRISTOL.—The Electric Light Committee, at a meeting on Saturday, confirmed their previous decision as to accepting the tender of Messrs. Siemens Bros. and Co. (Limited) instead of the lowest tender sent in, and decided to advertise for a switchboard and internal fittings of the central station to complete the plant. Some discussion ensued as to the terms on which the electric light will be supplied to private consumers, but no decision was come to.

BROMLEY.—It will be remembered that the Local Board endeavoured to ascertain the support likely to be accorded by the principal public frontages in the district to their electric lighting scheme. The Electric Lighting Committee have had the replies to the circular sent out by them under their consideration, but have deferred the matter for the present, pending the Local Government Board inquiry as to the acquisition of the proposed site for a central station.

BURY.—A long discussion took place at the last meeting of the Town Council on the subject of the electric lighting of the town, in the course of which complaint was made that the progress made in the discussion of the subject was not satisfactory. It was ultimately agreed that a committee, consisting of Aldermen Maxwell and Brierley and Messrs. Byrom and Hopkinson, be appointed.

BURGLARY AND THE TELEPHONE.—A daring attempt at burglary was made on Wednesday on the premises of Messrs. Walter Cross and Co., jewellers, of Holywell-street. The thief having obtained entry to the premises attempted to open one of the show cases which was connected up to a number of burglar alarms which were only fitted a day or two previously, these commenced ringing and the sound was communicated by telephone to the second place of business of Messrs. Cross in High-street, Bloomsbury; the thief hearing the ringing of the bells cut the telephone wires, but the telephone communication and the noise made by the ringing of the bells had aroused a dog in the Bloomsbury establishment, which succeeded in awakening one of the members of the firm, who hastily made his way to Holywell-street, accompanied by the police. The burglar had, however, taken alarm at the ringing of the bells, and had effected his escape, leaving behind him the implements of his profession and some wearing apparel which may assist in his capture.

CARDIFF.—The *Western Mail* of the 11th February contains an account of an interview with Mr. Massey and Mr. Harpur, and sets out in detail these gentlemen's views on the subject of the utilization of water-power for the Cardiff lighting.

DEWSBURY.—The Lighting and Water Committee ecommended at a meeting of the Town Council on Thursday that the site of the old gas works be utilised for the new central electric light station, which, after some discussion, was agreed to.

DOLCOATH.—The *Mining Journal* states that the electric lighting of Dolcoath will soon be accomplished. Engines are being fixed and the plant is nearly ready for placing. The Cornish miners are represented as being very friendly to the light.

DOLGELLY.—The Local Board, having recently received a communication asking for the sole right of supplying electric light within the Board's district for a term of 21 years, have replied that they could not entertain the proposal.

DORSET.—Mr. E. Dale, of Sherborne, Dorset, writes to say that it is contemplated supplying the Dorset County Police with electric lamps to be attached to the policemen's belts. Mr. Dale further states that by means of an improved primary battery, these lamps are to be charged by the police themselves.

DUNDEE.—In reference to a note in our last issue stating that the tender of Messrs. Lowdon Bros., had been accepted for the lighting of the Town House and offices by electricity, we are asked to state that this is incorrect, and that Messrs. James Maxwell and Son, of King's-road, Dundee, are the contractors. The number of lamps is to be 109 16-c.p. and 3 200-c.p., the contract price being £140.

EDINBURGH.—It was proposed that circulars should be sent out in order to ascertain how many consumers were disposed to use the electric light, should the Town Council ultimately resolve to undertake the lighting, but after consideration it has been decided to consult further with the experts, whose advice is to be taken upon the whole matter.

"THE ELECTRICAL WORLD" OF NEW YORK.—This journal, in its last issue, notifies a new departure. Following the lead of several engineering and electrical journals in this country, it is proposed to add a "Review of Reviews" corner in the *World*, under the supervision of Mr. Carl Hering.

EXETER.—Mr. J. H. Stanbury, Proprietor of the Royal Clarence and Half Moon Hotels, which have for some time been supplied with the electric current by the local electric light company, has recently laid a cable between the two buildings, and they are now lighted by an independent installation. A 17-H.P. Tangye gas engine drives a Royce dynamo, and there are 54 Crompton-Howell accumulators, which will sustain 100 16-c.p. incandescent lamps for 8 hours. The installation comprises about 300 Edison-Swan incandescent lamps. Mr. A. Stanbury, of Liverpool, has plannedand supervised the work of the installation.

FOOTBALL BY THE ELECTRIC LIGHT.—Hull is losing no time in taking full advantage of the electric light, and its latest departure is a football match, played on Wednesday night last week in the enclosure of the Hull Football Club. Eight 1,000-c.p. arc lamps surrounded the field—three on each side and one at each end. The players found that rather more light would have been advantageous, but the affair altogether was a distinct success.

HAMMERSMITH.—The Electric Lighting Committee of the Vestry have recommended that an expenditure not exceeding £100 be made for the purpose of making experiments for utilising the dust and house refuse for producing power for electric lighting purposes.

HARROGATE.—The Town Council have requested the Board of Trade to grant them an extension of time to consider the question of working their Provisional Electric Lighting Order.

HENLEY.—The Town Council at their last meeting received the report of the Lighting Committee, which recommended the Council to apply to the Gas Committee for a reduction in the price at present paid for gas. The report also recommends: "That the Town Clerk be directed to make enquiries as to the probable cost of obtaining a provisional order for electric lighting." In moving the adoption of this report, Alderman Watts stated that the Committee had had under their consideration the application by numerous local bodies throughout the Kingdom for provisional electric lighting orders, and he thought that Henley offered sufficient inducements in the way of probable consumption to justify them in taking the matter into earnest consideration.

Hosted by Google

HECKMONDWIKE.—The result of the poll of the ratepayers for and against the proposed introduction of the electric light into Heckmondwike by the Local Board has been declared—against 725, for 694; majority against 31. The number of papers returned unfilled up was 523, showing that nearly one-fourth of the electors took no interest in the question either way.

HERTFORD.—The Lighting Committee reported at the last meeting of the Town Council that they had visited several central electric light stations for the purpose of obtaining practical information upon the subject, and hoped at an early date to present to the Corporation a report that would enable them to come to a definite conclusion with regard to the matter.

ISLINGTON.—A letter to the Vestry from the Holloway Electricity Supply Company (Limited), asking for the Vestry's consent to an application for an Electric Lighting Order, has been referred to the Electric Lighting Committee.

LECTURES.—Recent lectures include a Cambridge University Extension series on "Electricity and Magnetism," by Mr. Knowles, at Stockport; and a course at Leeds, by Dr. Stroud, of Yorkshire College.

LIVERPOOL.—It will be remembered that the City Council have refused the Liverpool Electric Supply Company the powers asked for to lay two surface mains across Sefton Park. The matter again came up for discussion at the last meeting of the Parks, Gardens, and Improvement Committee, and it was ultimately agreed to refer the matter back to the committee for reconsideration. There seems a disposition on the part of the members of the committee to meet the Company on condition that certain stipulations are inserted in the agreement.

LIVERPOOL OVERHEAD RAILWAY.—Messrs. Maunsell Mercier and Co., of Deansgate, Manchester, have supplied the whole of the station-to-station electric bell signals, and the electric bell communications in the cars for the Liverpool Overhead Railway Company.

LLANGOLLEN.—The Local Board has formed itself into a committee to consider the question of the lighting of the town of Llangollen by electricity.

"THE LOCAL GOVERNMENT ANNUAL."—We have received a copy of the Local Government Annual for 1893, which will be found of service to those contracting firms desiring to communicate with Local Authorities throughout the country. The book is published at the offices of the *Local Government Journal*, Dorset House, Salisbury-square, Fleet-street, E.C., price 1s. 6d.

"LONDON."—This is the title of a new paper, published chiefly with the object of reporting the proceedings of the London County Council, and to aid the advancement of civic and social progress. The first number is well printed, and can be safely commended to those of our readers interested in London municipal matters. The price of the journal is 1d.

PORTRUSH.—On the proposal of Capt. Watt, the Town Commissioners have decided to advertise for tenders for the lighting of the town by electricity.

THE PRESS AND ELECTRIC LIGHTING.—As evidence of the continued interest in the subject of the introduction of the electric light throughout the country, we have recently called attention to various series of articles in the principal provincial journals. The *Yorkshire Weekly Post* is inserting a series of articles on this subject, popularly written, and similar in character to those to which we have previously referred.

ST. JAMES'S VESTRY, LONDON, W.—The recommendation of the Lighting Committee "that each member of the Vestry be furnished with a copy of the report issued by the Electricity Department of the St. Pancras Vestry, showing the result of the first year's work of that Vestry's electric supply undertaking," was adopted at the last meetng.

ST. OLAVE'S, SOUTHWARK.—The Vestry have decided to continue their opposition to the City and South London (Islington Extension) Electric Railway Bill.

SHIP ELECTRIC LIGHTING.—The Liverpool Salvage Association's new wreckage steamer "Ranger" has recently left Liverpool for the purpose of rendering assistance to the stranded steamer "Cuban." The "Ranger" has a most complete electric light installation on board, including a search-light of 22,000 candle power fitted at the foremast, arc lamps of 5,000 candle power at each masthead for the working of cargo, and a number of submarine electric lamps.

SUNDERLAND.—The Highways Committee have resolved to recommend the Town Council to request Prof. A. B. W. Kennedy to draw up a scheme with a view to carrying out their Provisional Order.

SUTTON.—The Local Board had before them at their last meeting an inquiry whether they would transfer their powers under their Provisional Order to a company, provided the expense incurred in obtaining the Order were paid, and after some discussion a special committee was appointed to go into the question. The Sutton Gas Company asked if the Board would assist them in obtaining the necessary powers to supply electricity, and the letter was referred to the General Purposes Committee.

TELEPHONIC COMMUNICATION.—The St. Albans County Police Office has been placed in telephonic communication with Hatfield, Watford, and Rickmansworth, and can also communicate with the private residence of the inspector in charge and the Clerk of the Peace for the district. Hertford will shortly be connected up on the system.

TIVERTON.—A local journal of the 11th instant contained an account of the draft scheme for the proposed electric lighting of Tiverton, from which it would appear that the total cost of the proposed premises, plant, and installation would be £17,000. The scheme was laid before Mr. de Ferranti, whose opinion, the journal in question states, has been received. The *Western Times*, however, states that the draft scheme is unauthorised.

TUNBRIDGE WELLS.—The Town Council have had under discussion Mr. Preece's report on the best manner of exercising the powers conferred by the Electric Lighting Provisional Order of 1891. The Electric Lighting Committee of the Council recommended the adoption of the report and the approval of the plans prepared by Mr. Preece for the purpose of establishing electric lighting works, and also on application to the Local Government Board for sanction to borrow £13,000 for the purposes of the order. The motion that the recommendations be adopted was carried, and the debate on the subject of the report was adjourned for a month.

MR. MCWHIRTER.—A complete mining installation for lighting, hauling, and pumping has been completed at the Loganlea Colliery, West Calder, by Mr. McWhirter, of The Faraday Electrical Works, Govan, Scotland. The work comprises a 70 H.P. Faraday compound wound dynamo and two motors of the same type, three 2,000 c.p. arcs, and a large number of incandescents. The haulage plant is capable of dealing with 200 tons per day, and owing to the satisfaction this plant has given, a considerable extension is now being made. It is claimed for this colliery that it is one of the most completely equipped in the East of Scotland.

ROCHDALE.—Mr. J. K. Grindrod has recently installed the electric light in the extensive corn mills of Messrs. Cunliffe and Swyre, and Messrs. C. A. Parsons and Co. have supplied a powerful search light for the mill of Messrs. Kelsall and Kempe, the latter also installing the electric light in the mill, about 500 incandescent lamps being used.

RUNCORN.—It has been proposed that Messrs. A. Hall and Co., of Liverpool, be instructed to prepare a complete report, specification, and estimate of the proposed electric lighting for the public streets, and a Special Committee of the Board of Commissioners has been appointed to deal with the matter. This Committee have been authorised to obtain information from other Local Authorities who have had practical experience of the working and cost of the electric light prior to the firm of engineers being engaged to make the report referred to.

WALSALL.—The Town Council have resolved to give a fee of £350 to Mr. F. Brown, of Birmingham and Walsall, as consultant in the new electric light scheme, which it is contemplated will cost between £15,000 and £20,000. It was stated that the works would be completed in a little over twelve months, and that for three months after the completion Mr. Brown's service would be retained.

WESTON-SUPER-MARE.—The Electric Lighting Inspection Committee having received a letter from the Brush Electrical Engineering Company (Limited) offering to submit a proposal for the transfer of the Commissioners' Provisional Order to a local company to be formed by them, the clerk was instructed to reply to the Brush Company to the effect that the Board were open to consider such a proposal, but that the proposition for the payment for goodwill at a valuation on the expiration of the term fixed would not be entertained.

WHITEHAVEN.—At the last meeting of the Town Trust the minutes of the Electric Lighting Committee came up for discussion, which included a lengthy correspondence with the contractors for laying the mains. Considerable progress has been made with the works at the central station.

WREXHAM.—The Wrexham Electric Lighting Company has given up the Wilderness Mill part of their electric lighting scheme, and are confining their attention to the lighting of the borough. The Company are, we understand, prepared to negotiate with the Corporation for the purchase of the undertaking. A letter to this effect was referred to the Lighting Committee of the Town Council.

COMPANIES' MEETINGS & REPORTS.

Kensington and Knightsbridge Electric Lighting Company.

The sixth ordinary general meeting of this Company took place yesterday at No. 1, Great George-street, Westminster, Mr. Granville R. Ryder presiding.

The CHAIRMAN, in proposing the adoption of the report and accounts, thought they would agree with him in considering that substantial and steady progress was shown by the statement submitted. With reference to the houses and shops taking the light, the number had increased from 436, at the end of 1891, to 550 in the past year, the 8-c.p. lamps had risen from 38,408 to 47,441, and the output of units had jumped from 385,051 to 535,343. The gross earnings for 1891 were £12,266, whereas last year they amounted to £16,628, an increase of £4,361; and the net profits had risen from £4,381 to £6,828. A satisfactory point in these figures was that the ratio of profit to the gross receipts had considerably increased—from 36 per cent. in 1891 to 42 per cent. in 1892. That point might be further elaborated by this fact also—that the increase in the net profit of £2,446 might be put against the advance of £4,361 in the gross earnings; and in that case the increase would stand at about 56 per cent. of profits as against gross earnings. The capital expenditure during the year had been £12,800, of which £4,441 had been on mains and £3,764 on plant. He afterwards dealt with the revenue account, and expressed gratification at the first item on the expenditure side—manufacturing electricity, coal, oil, water, waste, wages, and sundries. This item stood at £3,746, compared with £4,067 in the previous statement, so that with an increase of output of very nearly one-third, the expense of producing the expense of producing the electricity had been about £300 less. He also referred with satisfaction to the acquisition by the Company of a district which formerly belonged to the Chelsea Company, and said that on the purchase price they expected to obtain a return of 10 or 12 per cent.

Mr. G. H. HOPKINSON seconded the motion, which was adopted, and resolutions were also passed declaring a dividend of 4 per cent. per annum on the ordinary shares, voting the Directors £350 remuneration for their services for the past year, and re-electing the retiring Directors and auditors.

[*We shall publish a full report of this meeting in our next issue.*]

India Rubber, Gutta Percha, and Telegraph Works Company (Limited).

The twenty-ninth ordinary general meeting of this Company was held at the City Terminus Hotel, on Tuesday, under the presidency of Mr. S. William Silver.

The SECRETARY (Mr. William J. Tyler) read the notice calling the meeting, and the report of the Directors was taken as read.

The CHAIRMAN said: The report is a very brief one, but I hope you will agree with me that it is satisfactory, as it confirms the hopes expressed when we last had the pleasure of meeting. The result of the year's transactions—after carrying to reserve all the premium on the new capital issued, with a portion of the profit made—justifies our recommending the same dividend as heretofore, with a bonus, carrying forward an amount fully as large as we did a year ago. The additional capital has been well employed. It has enabled us from time to time to lay in large stocks of raw material under favourable circumstances, and thus to compete successfully in the hard-fought battle of trade, finding remunerative employment for our works, which, I am happy to say, are in a highly efficient condition. We have manufactured over 3,000 miles of submarine telegraph cable, and, I am glad to say, without a fault, and well within the contract time. The same may be said of our French factories, which have been doing good work. With the sinews of war, in the form of ample capital, and the masterful mind of my friend the Managing Director in command, I have no fear as to the future of this undertaking. I have much pleasure in recommending for your approval the following resolution:—

"*That the report and accounts now presented be received and adopted, and that a dividend of 5 per cent. and a bonus of 2½ per cent., together 15s. a share, free of income-tax, payable on the 15th inst., be now declared.*"

Mr. ROBERT HENDERSON seconded the motion.

The CHAIRMAN said he would be very happy to hear any remarks that any shareholder might have to make; but there being no discussion he put the motion in the usual way, and it was carried unanimously.

The MANAGING DIRECTOR (Mr. Matthew Gray) proposed the re-election of Mr. Silver and the Hon. Henry Marsham to their seats at the Board.

Mr. ABRAHAM SCOTT expressed his pleasure in seconding the motion, and said that both gentlemen worked so well and so ably that he would be very sorry if they were not both re-appointed.

The resolution was carried unanimously.

The CHAIRMAN: In our joint names I thank you for this renewal of your confidence. I need hardly say that it will stimulate us to fresh exertions; and I hope that we shall meet under as favourable circumstances on the next occasion.

On the motion of Mr. MARTINDALE, seconded by Mr. COCHRAN, Mr. J. F. Clarke, of the firm of Messrs. Turquand, Youngs, Weise, Bishop, and Clarke, was elected auditor of the Company.

Mr. GEORGE HANBURY then proposed a vote of thanks to the Chairman and the Directors for the admirable way in which they had managed the Company's affairs. He had been a shareholder for many years, and although there had been some slight variations in the dividend, yet he was sure that

Hosted by Google

everyone would agree that it was a very steady and excellent investment and it seemed likely to continue so. He believed that while they had the same management of Mr. Gray, Mr. Silver, and the other members of the Board the same prosperity would attend the Company.

Mr. TREBLE seconded the motion, which was carried by acclamation.

The CHAIRMAN: It only remains for me to thank you for this fresh proof of your confidence. In doing so I think I ought to remind you of the stake which we have on this side of the table in the Company, and that our interests are identical with yours.

The proceedings then terminated.

City and South London Railway Company.

Pursuant to the Standing Orders of Parliament a special general meeting of the proprietors of this Company was held at the offices of the Company, 46, King William-street, on Thursday, February 16th, for the purpose of considering, and if thought fit, of approving a Bill now pending in Parliament, intituled—"A Bill to extend the time for the purchase of lands for and for the completion of the Subway or Underground Railway, authorised by the City and South London Railway Act, 1890." Mr. Sampson Hanbury presided.

Mr. W. F. KNIGHT (the Secretary) read the notice calling the meeting.

The CHAIRMAN: Gentlemen, in the absence of the regular Chairman of the Company, Mr. C. Grey Mott, I have been requested to take the chair at this Wharncliffe meeting, and I call upon the solicitor to explain the provisions of the Bill.

The SOLICITOR: The only practical provisions in the Bill are that the time for acquiring the land is extended to July 25, 1895, and the time for the completion of the works is extended to July 25, 1898. The other part of the Bill is only formal.

The CHAIRMAN invited discussion upon the proposal, and there being no remarks, he moved the approval of the above Bill, subject to such additions, alterations, and variations as Parliament may think fit to make therein.

Mr. TATE seconded the motion, which was carried; and a vote of thanks to the Chairman closed the meeting.

Liverpool Overhead Railway Company.

The half-yearly meeting of the shareholders of this Company was held at the Law Association Rooms, Cook-street, Liverpool, on Tuesday, Sir William B. Forwood, Chairman of Directors, presiding.

The CHAIRMAN, in moving the adoption of the report (which appeared in the last issue of *The Electrician*), stated that the Directors had met the shareholders so recently that he need not detain them with any lengthened remarks. The railway was now practically completed, and, as they knew, the formal opening took place on the 4th inst. The function was in every sense a great success, and he hoped that the eloquent and very encouraging words spoken by Lord Salisbury on that occasion would be remembered by all the shareholders, for the noble marquis spoke not only merely as an eminent statesman, but as one of the most able electrical experts in the country. Lord Salisbury had written him a letter, in which he stated, "I thank you heartily for a very interesting evening and day at the end of last week. It was one of the most interesting twenty-four hours I ever passed." The Directors were now busily engaged in completing the electric signals of the railway, the whole of which would be completed and connected by Thursday. They were also exercising the staff in their duties, and were that day running a five-minute service of trains. Of course they were carrying no passengers, because the railway had not been passed by the Board of Trade. They had made their preliminary examination, and when the electric signals were completed they were coming down to make their final examination. He thought he might say that the railway would be opened to the public on March 1st, and he hoped before that day they would be able to give an opportunity to the shareholders of having a private inspection of the railway, so that they might be able to make a test for themselves. The trials up to the present had been in every way satisfactory, both as to smoothness of running, perfect control over the trains, economy in the electric energy employed, the rapidity with which they could get up speed, and the high rate of speed attained. In all these cases the trials had exceeded their most sanguine expectations. It was also satisfactory to know that at the opening function they had almost all the leading experts of the country present, and it was the unanimous verdict of all those gentlemen that the work of the railway had been very well done, the ironwork of the main structure and the machinery in the generating station being all the subject of praise. That reflected very great credit upon their engineers, their contractors, and sub-contractors. Referring to reports in the newspapers, he assured them that the electric conductor could not and would not be a source of danger to any passenger. It was entirely out of the reach of the passengers, and if a passenger chose to stand upon it would simply give him a slight shock which would be rather beneficial than otherwise. The railway was constructed upon a corrugated floor, and it was stated in one of the newspapers that they were paying a heavy royalty to an *employé* of the engineers for the use of that form of structure. It was quite true that the chief of the staff in the employment of the engineers did patent the corrugated floor—and it was a very valuable patent—but the Directors had not had to pay a penny piece of royalty. There were a great many reports put out in reference to the railway, but they must not believe one of them. The railway was a thorough success from beginning to end. The only trouble they ever had had been a little delay in fixing the electric signalling, and he could now say they were promised that the signals would be in full working order by Thursday. Everything they had seen in connection with the railway led them to the belief that it would be a thorough success. The trains would be rapid, well under control at all times, and he was quite sure the service they would give to the public would be thoroughly appreciated.

Mr. JAMES BARROW seconded the motion.

In reply to questions, the CHAIRMAN said that the contractor had informed the Directors that it would take three months to complete the northern extension, but they had put it down at six months. The Directors had given instructions that day to the engineers to prepare the plans, so that the shareholders might take it that the work would be completed in six months from that day. In regard to a supposed difficulty as to the trains passing each other when meeting the Chairman said that their line was a full gauge one; they had six feet space between the rails, precisely as had the London and North-Western and every other company, and their carriages also were precisely the same width as the Pulman cars on the London and North-Western Railway; so that the statement which had been made was absolutely untrue. As to a platform being erected outside the lines, plans which had been before the Board of Trade and passed provided for a parapet on both sides of the lines. That was a considerable expense to the Company, but the Board of Trade put it upon them. It was part of the original plan and original contract, so that there had been no additional expense, and the Board of Trade had already passed the main structure.

The report was adopted unanimously.

Sir Wm. Forwood and Mr. Harold Brocklebank were re-elected Directors and Mr. J. S. Harmood Banner was reappointed auditor, and the proceedings closed with a vote of thanks to the Chairman.

General Electric Power and Traction Company (Ltd.)

The second ordinary general meeting of this Company was held on Tuesday last at Winchester House, Old Broad-street, the Right Hon. the Earl of Albemarle presiding.

The SECRETARY (Mr. J. Payne) read the notice convening the meeting, the report of the Directors and statement of accounts being taken as read.

The CHAIRMAN: Gentlemen, I am not going to make a great many remarks. I regret that it has been necessary to postpone this meeting so often, but it is well known to all of you, I think, that very great and serious changes have been made in our staff, and that many of those who take the liveliest possible interest in your affairs have been compelled to absent themselves through illnesss. One of our Directors, Lord Egerton of Tatton, whom we all highly esteem, is at this moment at Biarritz, suffering greatly in health, and I have received a telegram from him to-day, stating his full concurrence in the course that we are to pursue. I myself have been suffering for two years from a very severe illness, and have not been able to give recently the same attention to electric traction which has occupied my attention for many years past, as I used to do. The balance-sheet, together with the auditors' report, give such very full information in regard to the accounts of the Company that it is not necessary for me to say very much about them, but I am desirous of taking this opportunity of again pointing out to the shareholders that the large loss shown has not been entirely incurred by the operations of the year—more apparent than real. It will be observed that a sum of nearly £60,000 has been written off to capital account in respect of depreciation on plant and for the Barking undertaking, and that the patents and goodwill have been written down by £20,000. These are losses which the Directors think it well should be plainly recognised by the shareholders, but they are losses not in any way due to the management of the business. The trading account, it is true, shows a loss of £4,000, but this has arisen largely from exceptional causes, and the Directors hope that they will not recur. The expenses of the management may also appear high, but the greater portion of these items were incurred in the earlier part of the year, and latterly very considerable economies have been introduced. The Board have made an arrangement with the Electric Construction Corporation (Limited) by which that Corporation will for one year undertake the management of the Company for a fixed sum, which represents less than one-tenth of the amount charged for the management expenses for the past year. The Electric Construction Corporation (Limited), as a result of the changes which they are making in their own organisation, will be able, the Directors hope, to arrange for the efficient conduct of this Company's business, and the Directors will, in consultation with them devise a plan of action for the future, which the Directors hope will be beneficial in its results. The Electric Construction Corporation (Limited) are large shareholders in the Company, and have, therefore, every interest to improve the value of your property. But little progress has been made with electric traction, and although we are confident the systems we advocate would be of the greatest possible benefit to the shareholders, they are at the present moment practically in abeyance. We are bound to admit that the hopes we entertained in connection with this branch of our business have not been fulfilled. We have had promises from various quarters, and we have incurred considerable expense to demonstrate the advantages of electric traction as compared with the present system. We have seen no reason to change our opinions. Whether it is want of confidence, want of enterprise, want of capital, or the influence of vested interests which is so all powerful we cannot say. We do not feel justified in continuing to demonstrate at our own cost what should be obvious, and no doubt is obvious, to those entrusted with the management of our tramway systems. We had come to an arrangement with the North Metropolitan Company which would have enabled us to work even that small installation at Barking of five cars without loss, and possibly at a profit, but having had occasion to remonstrate with that Company on the disgraceful state of the permanent way, that Company withdrew from the arrangement, and the cars are at present stored at Millwall. That our complaints were justified is evidenced by the fact that before they could resume horse traction the whole of the roads had to be thoroughly overhauled. We con-

Hosted by Google

sider that the principle of runing cars at a mileage rate is altogether unfair to the electrical contractor, the greater the success the greater the loss to those who have to provide the electrical energy. It was notorious that the cars at Barking were constantly overloaded, but, of course, in such a case as this the police are not required to interfere. We have, in the course of this experiment gained some valuable experience, and I am advised that given an installation of, say, a dozen cars, with average gross receipts of, say, 11d. per car mile, which is much less than the receipts at Barking, the installation can be run at a profit to all parties concerned, and is certainly superior to horse traction. We must bear in mind that the vested interests involved must naturally tend to retard the introduction of electric traction, but time and the constant pressure of shareholders on the tramway companies will surely lead to the adoption of electric traction throughout the country. When that time comes we hope to get our share of the benefit. There is no doubt that in anticipation of a greater demand for machinery than has been experienced, our late Manager produced more stock than was strictly prudent; this we hope to realise, but meanwhile, acting on the advice of our auditors, and in accordance with our own views, we have thought it prudent to write it down to what may be considered an excessively low figure. The expenses in every branch have been cut down as low as possible. The losses on the year have been materially reduced. At the present moment our attention is devoted to the completion of the Copper Works at Millwall. Mr. Thomas Parker has joined the Board, and if properly worked there is every reason to hope the deposition of copper will form a most important branch of our business. If we should eventually determine to turn this copper into wire we do not anticipate any difficulty in placing all we can manufacture. The Kentish Town Works will be transferred to Millwall, and a considerable saving will be effected in rent alone. I beg to move the adoption of the report and accounts.

Mr. JAMES PENDER seconded the motion.

Mr. DUNN thought everything pointed to the fact that the property was taken over at too high a valuation, and said that the report should not be adopted until the capital was written down.

Sir HENRY C. MANCE said that such a course was rather premature, but no doubt it would eventually be adopted.

Mr. DUNN moved an amendment in effect to appoint a committee of shareholders to confer with the Board with regard to the reorganisation of the Company.

Mr. THOMAS seconded the amendment, and asked whether under the present circumstances of the Company it was the intention of the Board of Directors to forego their fees for the last eighteen months.

Sir HENRY MANCE explained that their late manager was somewhat sanguine in overestimating the value of the plant and machinery, and the Directors had acted conscientiously in appraising them at what was considered to be their true value. As to the fees of the Directors, those fees had been reduced, and even on the reduced scale they had not been taken. With regard to the suggestion as to a conference of shareholders with the Directors, he could only say that in the case of no other company had there ever been given a fairer explanation of all the items in the balance-sheet sent out to the shareholders. There was no information which he could give which was not clearly set forth in the report. They had strengthened the Board by electing to a seat Mr. Thomas Parker, who would no doubt materially aid them.

Mr. JAMES W. BARCLAY, while agreeing with the observations of Mr. Dunn, pointed out that the writing down of the capital and the reconstruction of the Company were expensive operations, and might be left over for another year.

The CHAIRMAN, in reply to a shareholder, said that the launch business on the Thames was likely to be a successful branch of the Company's business.

The amendment for the appointment of a committee of investigation was put and lost.

The original motion was then agreed to.

Mr. MORITZ IMMISCH proposed, and Sir HENRY C. MANCE seconded, the re-election of Lord Albemarle to his seat at the Board.

The motion was adopted unanimously.

Mr. J. PENDER next proposed and Mr. IMMISCH seconded, the re-election of Lord Egerton of Tatton, the other retiring Director.

The motion was agreed to *nem. con.*

The auditors (Messrs. Ward and Wilding) having been re-appointed, a vote of thanks to the Chairman and Directors brought the proceedings to a close.

Newcastle and District Electric Lighting Company (Limited).

The sixth ordinary general meeting of this Company was held on Monday at 57, Westgate-road, Newcastle. Mr. John D. Milburn in the chair.

The following report of the Directors was taken as read :—

"The Directors have pleasure in reporting that the supply of current continues to give satisfaction to the Company's consumers, and, although the present depression in trade has had the effect of somewhat crippling progress, the prospects of the Company continue satisfactory. The installations connected to the Company's mains during the year are equal to 3,500 10-c.p. lamps, bringing the total up to about 14,500, and 290,469 units of electrical energy have been supplied, as against 206,017 units supplied in 1891. During the past year 3,012 yards of main and branch piping have been laid, together with 6,146 yards of main and branch cable. A tunnel has now been completed from the Company's works to the river Tyne, and condensing plant is being erected to which water will be circulated direct from the river; it is expected that this plant will be in operation next month, and your Directors anticipate a considerable saving of both fuel and water. It is anticipated that there will be a great fall in the price of lamps during this year, which will greatly tend to further the interests of the Company. The gross earnings during the year amount to £2,139. 15s. 1d., and after paying interest and making provision for reserve fund, and writing off £59. 7s. 7d. from formation expenses, your Directors are able to recommend a dividend at the rate of 3 per cent. for the half-year ended December 31st (less income tax), which, together with the interim dividend paid in July last, makes the dividend 5½ per cent. for the year. Sir Benjamin C. Browne retires by rotation, but is eligible, and offers himself for re-election as a Director. The auditors, Messrs. Strachan and Co., also offer themselves for re-election."

The CHAIRMAN then said: The leading feature of the year's work is the payment of a little more dividend. This increase in the earning power is trifling, but it marks progress. The following figures will prove the steady progress we are making: Units sold, 1891, 206,017; in 1892, 290,469—increase, 84,452. Increase of output, 41 per cent.; increase in receipts, 23 per cent. Selling price, 1891, 5·309; selling price, 1892, 4·650—difference per unit, 0·659. Cost price, 1891, 3·420; cost price, 1892, 3·113—difference per unit, 0·307. You will see, therefore, that whilst our average price has been gradually reduced, the cost has likewise been reduced, and, by the introduction of the shaft and tunnelling to the Tyne and the new condensing plant, the cost of fuel is expected to come down to nearly one-half. This is a great economy, but nothing like the saving which will ensue by doubling the production of the current. Cheapness begets demand, and demand begets cheapness of production. In the summer months, when our output is only about 11,000 units per month, the cost of production is about 4½d. per unit. In mid-winter, when the output is 50,000 units, the price per unit comes down to 2d. It is obvious, therefore, that when we shall be able to supply 50,000 units per month, the average cost will be enormously reduced; and we hope at no distant date to be able to produce electric current at a net cost of 1d. to 1½d. It is, however, impossible to attain this end by hoping to sell the current for illuminative purposes alone, and we must look to other sources of demand, such as motive power, ventilation, &c. Electric cooking is now an established fact, and the method can be seen at the Victoria Hotel, where are introduced the best electric cooking appliances in the market. Sixpence per unit electricity, with a properly proportional installation, is equal to about 5s. per 1,000ft. of gas. The gas companies have not much to fear in the way of competition so long as the price of electric lighting stands at 5d. to 6d. What, however, we want to be at is to be able, profitably, to supply electricity for lighting purposes at 3d. per unit, equal to only 2s. 6d. per 1,000ft. of gas. This, as I think I have shown you, can only be done by increased demand for electric current and steady economy in working expenses. A great stimulus will undoubtedly be given to electric lighting by the termination in November next of the patents of the Swan-Edison lamps. In reference to the report recently made to the Watch Committee of this city by Mr. Lamb, the inspector of lamps, I have to say on behalf of this Company that we are prepared to prove that the right system has been adopted by this Company for public lighting, and that in no place in England have the lamps given greater satisfaction. We trust that the Watch Committee will soon make up its mind to take their electric lighting question into consideration.

Sir B. C. BROWNE, in seconding the motion, said they had considered very carefully before they increased their dividend, but they were fully justified in making that step forward.

The Directors' fees were increased from £105 to £210 per annum, the retiring Director and auditors were re-elected, and the proceedings closed with the usual vote of thanks to the Chairman.

Westminster Electric Supply Corporation (Limited).

The following report is issued by the Directors of this Company, and will be presented to the ordinary general meeting of shareholders to be held on Wednesday, the 22nd inst., at the offices, Eccleston-place, Belgravia, S.W., at 11 o'clock:—

The Directors are gratified in being able to state that the business of the Corporation continues to make steady and satisfactory progress. After very careful consideration, they decided, from the 1st July, 1892, to reduce the price of current from 8d. to 7d. per unit. The policy of reducing the standard charge which this Corporation initiated, has been fully justified by the increased consumption of current. On the 31st December, 1891, electric energy was being supplied from the Corporation's mains to the equivalent of 62,820 lamps of 8-c.p., and the supply increased to 98,686 on the 31st December, 1892. At the present time there are on circuit the equivalent of 102,743 lamps of 8-c.p., and applications have been received for a further 8,229.

The total length of roadway along which mains have been laid exceeds 33 miles, making about 130 miles of ways into which upwards of 97 miles of copper (strip and cable) have been drawn. The plant and machinery have been working satisfactorily throughout the year.

Since the last meeting of shareholders the building at Davies-street has been completed, the frontage having been finished as shops and chambers. In September last the chief office was transferred to Eccleston-place on the completion of the buildings there. Great convenience has been experienced by the concentration of the general staff under one roof.

As promised at the last meeting, the Directors offered £40,600 in £100 4½ per cent. mortgage debentures to the shareholders, by whom the issue was immediately taken up. The Directors were pleased to be able to pay a first dividend at the rate of 3 per cent. for the half-year ending 30th June last. The accounts now show a balance of £7,324. 8s. 9d. to the credit of net revenue and they recommend the payment of a dividend

Hosted by Google

at the rate of 4 per cent. for the past half-year, carrying forward a balance of £1,324. 8s. 9d.

In accordance with the Articles of Association two of the Directors, Messrs. J. Browne Martin and R. W. Wallace retire, but, being eligible, offer themselves for re-election. The auditors, Messrs. Cooper Brothers and Co., also retire, but, being eligible, offer themselves for re-election.

Electricity Supply Corporation (Limited).

The following is the report of the Directors of this Corporation for the year ended December 31st last, to be presented at the general meeting to be held at the Town Hall, St. Martin's-lane, London, W.C., to-day (Friday), at two o'clock :—

The Corporation are now supplying energy to 29,000 8-c.p. lamps, an addition of 7,000 since May last, or an increase at the rate of or about 32 per cent. on the number then supplied. Applications have been received and negotiations are pending for a substantial addition to this number. Additional mains to the extent of about two miles have been laid, making a total of upwards of eighteen miles of mains now laid.

Out of the available profits the Directors, after providing for the interim dividend up to June 30, 1892, and writing off the debit balance brought forward for 1891, propose to declare a dividend for the year up to December 31, 1892, at the rate of 5 per cent. on the capital from time to time paid up, and to carry forward the balance.

The Directors have every reason to be satisfied with the progress and future prospects of the Company.

The Directors retiring by rotation are Mr. George Henry Brougham Glasier and Mr. Isaac Percy Mendoza, who, being eligible, offer themselves for re-election. The auditors, Messrs. O. R. Johnson and Son, also retire and offer themselves for re-election.

NEW COMPANIES, STATUTORY RETURNS, &c.

[*In addition to the information given under this heading, detailed particulars of many of the Companies whose returns appear below will be found in* "THE ELECTRICIAN" ELECTRICAL TRADES' DIRECTORY AND HANDBOOK, 1893, pages 320-348, *&c., &c.*]

GEORGE MORITZ (LIMITED).—This Company was registered on the 9th inst., with a capital of £5,000 in £1 shares. The objects are to acquire the goodwill of the business of an electrical engineer, dealer in electrical appliances, fittings, and instruments, &c., now carried on by George Moritz, under the style or firm of "The Manchester and Liverpool Electric Engineering Company," at Manchester, Liverpool, and elsewhere ; and to carry on in all or any of its branches the business of electrical and mechanical engineers, electricians, suppliers of electricity, and manufacturers of and dealers in electric, magnetic, telegraphic, telephonic, and other appliances and apparatus, and of steam, hydraulic, pneumatic, or other engines, machines, appliances, and apparatus.

JAMES SMYTH AND SONS (LIMITED).—This Company was registered on January 31st, with a capital of £25,000, in £50 shares, to carry on the business of general and electrical engineers, at Peasenhall, Suffolk.

OVERTON, BANGOR AND DISTRICT GAS COMPANY (LIMITED).—This Company was registered on the 3rd inst., with a capital of £1,000, in £1 shares, to light with gas, electricity, oil, or other illuminating power, the roads, buildings, &c., in the parishes of Overton and Bangor, and to manufacture, work, buy, sell, let on hire, and deal in lamps, fittings, instruments, and other apparatus relating to or connected with the generation, supply, distribution, accumulation, and utilisation of gas and electricity.

ROLLASON AND SLATER (LIMITED).—This Company has been registered, with a capital of £30,000, in £10 shares, to carry on business as iron and brass founders, boiler makers, iron and steel plate manufacturers, mechanical and electrical engineers, wire drawers, &c., at Birmingham and Wombridge.

SILMAN BROTHERS (LIMITED).—This Company was registered on the 6th inst., with a capital of £1,000, in £1 shares, to carry on business as mechanical and electrical engineers at Moseley-street, Birmingham.

SOUTHERN CONCESSIONS SYNDICATE (LIMITED).—This Company includes among its objects the financing of electrical, telegraphic, and telephonic undertakings and companies. Capital, £120, in £1 shares.

WALLIS AND STEEVENS (LIMITED).—This Company was registered on the 6th inst., with a capital of £60,000, in 440 Preference shares of £100 each, and 1,600 Ordinary shares of £10 each, to carry on the business of mechanical, consulting, electrical, and general engineers, at North Hants Iron Works, Basingstoke.

BRITISH ELECTRICAL INSTALLATION CONTRACTORS (LIMITED).—At meetings of this Company, held on January 14th and February 4th, it was resolved and confirmed that the Company be voluntarily wound-up, and that Mr. W. J. Hill, 50, Foregate-street, Worcester, be the liquidator.

J. E. H. GORDON AND CO. (LIMITED).—A petition for the compulsory winding-up of this Company (in voluntary liquidation) was presented on the 8th inst. by Messrs. John Tullis and Sons, of Glasgow, and is down for hearing at the Royal Courts of Justice, London, on Monday next, the 20th inst.

LANCASHIRE AND YORKSHIRE ELECTRIC LIGHTING COMPANY (LTD.).—The annual return of this Company, made up to July 12, 1892, was filed on January 30, 1893. Out of a capital of £100,000, divided into 20,000 shares of £5 each, 127 shares have been taken up, and a call of £2. 10s. per share made, resulting in the payment of £315, and leaving £2. 10s. in arrears.

LAURENCE, SCOTT AND CO. (LIMITED).—The annual return of this Company, made up to December 23, 1892, was filed on January 12. The Company was registered in August, 1888, with a capital of £30,000, in £10 shares. At the time of making up, 1,406 shares had been taken up, of which 500 had been issued as fully paid. Upon the remaining 906 shares, the full amounts have been called, and all calls (£9,060) paid.

MULHOLLAND, MAUGHAM, AND CO. (LIMITED).—The annual return of this Company, made up to November 22, 1892, was filed on December 7th following. The Company was registered on July 29, 1890, with a capital of £5,000, divided into 120 founders' and 380 ordinary shares of £10 each. At the time of making up, 120 founders' and 1,678 ordinary shares were taken up, and upon the founders' shares the full amounts have been called, while upon the ordinary shares £5 per share has been called, resulting in the total of £2,035.

NEWCASTLE-UPON-TYNE ELECTRIC SUPPLY COMPANY (LIMITED).—The annual return of this Company, made up to February 2nd, was filed on the 7th, out of a capital of £50,000 in £5 shares, 6,104 shares have been taken up, of which 43 shares have been issued as fully-paid. Upon the remaining 6,061 shares a call of £4 per share has been made, resulting in the payment of £25,984, which includes a sum of £1,340 paid in advance of calls.

PERU TELEPHONE COMPANY (LIMITED).—The annual return of the above-named Company, made up to January 14th, has been filed. Out of a total capital of £100,000, divided into 20,000 shares of £5 each, only seven shares have been taken up, no calls made, and nothing paid, the original signatories to the Memorandum of Association being the only shareholders.

POOLE AND WHITE (LIMITED).—Mr. Edwin Wilding, Bloomsbury Mansions, Hart-street, Bloomsbury, has been appointed liquidator in the winding-up of the Company.

QUEEN ANNE'S MANSIONS LIGHTING AND HEATING COMPANY (LIMITED).—The annual return of the above-named Company, made up to December 28, 1892, has been filed. At the time of making up, all the shares had been taken up and all issued as fully paid.

ST. LUKE, CHELSEA, ELECTRIC LIGHTING COMPANY (LIMITED).—By an agreement made November 24, 1892, and filed on December 9th, it was agreed that this Company shall purchase from the Cadogan Electric Light Company (Limited) and its liquidator the lease of the premises at 91, Manor-street, Chelsea, S.W., and the powers granted by the Vestry of Chelsea, for the erection and maintenance of electric lines and works, and those granted by the Vestry of St. George, Hanover-square, for the construction and maintenance of a main under footway in part of Belgrave-square, and also the business, goodwill, plant, cables, machinery, stock in trade, book and other debts, &c., of the old Company. The consideration for the said sale is the payment of £4,250 in cash, and the allotment of 455 fully paid £10 shares, Nos. 1 to 455 inclusive, in such manner as the liquidator may direct. The annual return of the St. Luke, Chelsea, Electric Lighting Company, made up to January 11th, has been filed. At the time of making up the seven signatories' shares were the only ones taken up, and no calls have as yet been made. The above agreement, therefore, had not been put into effect at the time of making up the return.

VARLEY'S ELECTRIC PATENTS PROPRIETORY (LIMITED).—A meeting is to be held at 527, Mansion House-chambers, E.C., on March 14th, at 12, to receive an account of the winding-up.

CITY NOTES, &c.

CITY AND SOUTH LONDON RAILWAY COMPANY (LIMITED).—The traffic receipts for the week ended February 12th were £952, as against £881 for the corresponding period of last year, being an increase of £71. The total receipts for half-year amount to £5,862, against £5,033 in the corresponding period of 1892, being an increase of £829.

COMPAGNIE L'INDUSTRIE ELECTRIQUE DE GENEVE.—The receipts of this Company for 1892 were 177,586fr., and the expenses 87,816fr., or a balance of 89,770fr., which is 17,447fr. more than the previous year's balance.

CRYSTAL PALACE COMPANY.—In the course of his address to the shareholders of this Company, at their meeting last week, Mr. George Rait stated that, from a scientific point of view, the Directors considered the Electrical Exhibition held at the Palace in 1892 had been an enormous success, but from a financial point of view it had been an enormous failure ; besides which the Exhibition had blocked up the space, and they had, therefore, been unable to hold other shows.

MUNTZ'S METAL COMPANY (LIMITED).—For the past year a dividend of 10 per cent. per annum is proposed, leaving £15,781 to be carried forward.

PHOSPHOR-BRONZE COMPANY (LIMITED).—After placing £1,000 to the credit of the contingency fund, the Directors, in their annual report, recommend a dividend of 1¼ per cent., carrying over a balance of £134.

Hosted by Google

SOCIETE CENTRALE D'ELECTRICITE.—A Company has been formed with a capital of 120,000fr. for the creation and exploiting of electrical works in the towns of the departments of the Rhône, the Loire Haute Loire, Saône-et-Loire, Ain, Jura, Isère, and Ardèche. The offices are at Lyons.

WESTERN AND BRAZILIAN TELEGRAPH COMPANY (LIMITED).—The traffic receipts for the week ended February 10, 1893, after deducting 17 per cent. of the gross receipts payable to the London Platino-Brazilian Telegraph Company (Limited), were £3,616.

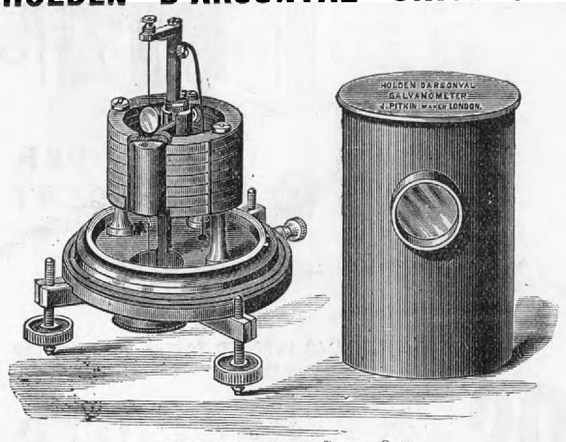
HOLDEN D'ARSONVAL UNIVERSAL DEAD BEAT REFLECTING GALVANOMETER.



INSTRUMENT WITH COVER OFF.

As supplied complete with Three Coils, Shunts, Resistances, and Self-locking Key, it is

The Best Galvanometer for Zero Testing.
The Best Galvanometer for Direct Measurements.
The Best Galvanometer for Measuring Large or Small Currents by the Shunt Method, from 1 to 1,000 Amperes.
The Best Galvanometer for Measuring E.M.F. from ·001 to 100 Volts.

Prof. W. AYRTON, Pres. I.E.E., speaking at the Institution on 26th Nov., 1891, said:—"*The deflection is larger than we have obtained with any other D'Arsonval of anything like the same size. . . . . Many times as sensitive as the Carpentier pattern for the same periodic time and resistance of coil. . . . . The method of construction has the great convenience that the coil, with its top and bottom supports, can be at once bodily withdrawn. . . . . .*"

As supplied to H.M. Govt.; The Central Institution; City Guilds; Electrical School, Chatham; R.A. College; Yorkshire College, &c.; and to Prof. Ayrton, F.R.S.; Prof. Fleming, F.R.S.; Sir T. Bazley, Mr. J. W. Swan, and many others.

EDWARD RUSHTON and SON have received Instructions from the National Electric Supply Company (Limited), to SELL by AUCTION, on WEDNESDAY, March 1st, 1893, on the premises of the North of England Wagon Works, Strand-road, Preston, to where the plant has been removed for convenience of Sale, the VALUABLE ELECTRIC LIGHTING PLANT, &c., all of which is in first-class working condition, including:—

MARSHALL'S PORTABLE ENGINE, 30 nominal H.P., Loco. Boiler 9ft. long, Engines 12½in. cylinder, 20in. stroke, about 4 years old.

The PORTABLE "ROBEY" ENGINE (Semi Portable), 14 nominal H.P., Loco. Boiler and Horizontal Engine, 9in. cylinder, 12in. stroke, about 8 years old.

TWO "BLAKEY-EMMOTT" No. 5 Shunt-wound DYNAMOS, 110 volts, 120 amp., and ONE "BLAKEY-EMMOTT" 4-pole Shunt-wound DYNAMO, 140 volts, 350 amp.

About THREE MILES of COPPER CABLE, and other Electrical Apparatus.

The foregoing is a COMPLETE INSTALLATION for the supply of current to 1,000 16 c.p. Incandescent Lamps, and is admirably suited for the Electric Lighting of some small town or village, exhibition, large works, &c.

Sale to commence on the conclusion of the Sale of Wood Working Machinery at the Waggon Works aforesaid.

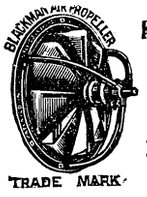
May be viewed any day prior to Sale.

Catalogues and other information may be had from the Auctioneers, 13, Norfolk-street, Manchester (T. N.775); and 21, Richmond-terrace, Blackburn (T. N.65).

PRELIMINARY ADVERTISEMENT.

NATIONAL WORKMEN'S EXHIBITION, ROYAL AGRICULTURAL HALL, from June to August, 1893. Under the auspices of the London Trades Council. To be opened by H.R.H. the Prince of Wales.

Particulars as to TENDERS for the ELECTRIC LIGHTING to be obtained from the Consulting Engineer, Mr. J. G. LORRAIN, M.Inst.E.E., M.Inst.M.E., Norfolk House, Norfolk-street, Strand, London, W.C.



TRADE MARK.

Electric and other works for Local Authorities, Promoters, &c., undertaken and financed.

35, PARLIAMENT STREET, LONDON, S.W.

BRISTOL ELECTRIC LIGHTING.

CONTRACT FOR SWITCHBOARDS, &c.

The BRISTOL URBAN SANITARY AUTHORITY are desirous of receiving TENDERS for the SUPPLY, DELIVERY, and ERECTION of SWITCHBOARDS, TERMINAL BOARDS, TRANSFORMERS, and other articles at the Central Electric Lighting Station and sub-Stations.

Tenders must be made on the prescribed Forms, and delivered at the Offices of the Authority, 51, Prince-street, Bristol, by WEDNESDAY, the 15th of March, 1893, endorsed "Tender for Switchboards."

The lowest or any Tender will not necessarily be accepted.

The Specification, Plans, and Form of Tender may be obtained at the Offices of the Sanitary Authority, on payment of £2, which will be returned on receipt of a bona fide Tender.

D. TRAVERS BURGES, Town Clerk.

51, Prince-street, Bristol, February, 1893.

COUNTY BOROUGH OF HUDDERSFIELD.

ELECTRIC SWITCHES, &c.

The CORPORATION OF HUDDERSFIELD are prepared to receive SAMPLES and TENDERS for the supply of MAIN SWITCHES and MAIN FUSES for Controlling the Supply of Electrical Energy to Consumers' premises.

Full particulars may be obtained on application to the Borough Electrical Engineer.

Samples and sealed Tenders to be forwarded to Mr. A. B. MOUNTAIN, Borough Electrical Engineer, Gasworks-street, Huddersfield, not later than WEDNESDAY, the 15th March, 1893, and the tenders must be endorsed "Main Switches, &c."

By Order,

H. BARBER, Town Clerk.

Town Hall, Huddersfield, 15th February, 1893.

SITUATIONS VACANT AND WANTED, &c.

ASSISTANT TELEGRAPH SUPERINTENDENT WANTED for India. Must be thoroughly trained in both out-door and mechanical shopwork and capable of undertaking the duties of the Superintendent when required. Candidates should state their age and experience.—Applications must be made in writing to Mr. GEORGE BERKLEY, 57, Charing Cross, London, S.W., from whom particulars as to terms and engagement may be obtained.

ELECTRICIAN WANTED at the COUNTY ASYLUM at LANCASTER to take charge of a 300-light plant. Must be competent to keep telephones and electric tell-tales in order, and will be required to reside in the Asylum and give his whole time to his duties.—Apply, stating salary required, MEDICAL SUPERINTENDENT, County Asylum, Lancaster.

WANTED an APPOINTMENT as SHOP FOREMAN. Used to Electric and General Engineering. Excellent testimonials.—"VOLTA," 2, Warwick-place, Bedford-row, W.C.

SALE OF PATENT.—The English Patent of an Electrical Apparatus affording safety against thieves, burglars, &c., is TO BE SOLD.—Inquire, W. RICHTER, Avondale, Batheaston, Bath.

ELECTRIC LIGHTING and BELL-WORK BUSINESS FOR DISPOSAL, London, W. Excellent premises consisting of good modern-fronted front shop and large light dry basement; moderate rent. To an immediate Purchaser a good discount will be taken from cost price of goods, or valuation. Satisfactory reasons given for disposal; about £500 will complete the purchase.—Apply, by letter only, to "M. E.," care of Mr. John R. Gale, 33, Cannon-street, London, E.C.

THE ELECTRICIAN:

A WEEKLY ILLUSTRATED JOURNAL OF

ELECTRICAL ENGINEERING, INDUSTRY AND SCIENCE.

No. 771.—Vol. XXX. FRIDAY, FEBRUARY 24, 1893. PRICE FOURPENCE.
Annual Subscription (U. K.), 19/6

NOTES.

We heartily congratulate the *Electrical Review* upon the result of the libel case heard last week. Being an action brought by Mr. Harness against his critics in the name of an unfortunate medical man the case was unsatisfactory, but still more unsatisfactory was it as an attack by these critics upon the Harness belt, backed though they were by scientific men of every standing. The onus of exposing medical quacks ought not to be thrown on electrical journals; theirs is the sufficiently serious responsibility of checkmating charlatans connected with the electrical industry, and action should long ago have been taken by the Medical Association or some other wealthy medical body. To fight a man like Mr. Harness must be an expensive matter, and a difficult one, when only indirect thrusts are possible. It appears that the costs in this case cannot be recovered, since Dr. Tibbits, whom none could see without a feeling of pity, is a man of straw; Mr. Harness was financing the case, but cannot be called upon for costs. When Mr. Bankes, for the defence, clearly stated that it was his intention to prove that the whole system was a fraud, the learned counsel for the plaintiff were placed in a most awkward position, for they were merely appearing for Dr. Tibbits in a prosecution for libel. The scientific evidence given in this case will be available for use in the civil proceedings which are being instituted against Mr. Harness, but, as we remarked on the occasion of the County Court case of misrepresentation by the Medical Battery Company, the vendors of Harness belts, we hope that the subject of these impostures may lead to a successful Treasury prosecution.

The three companies to the accounts of which we referred last week have since held their meetings, but nothing of particular importance transpired. At the Kensington and Knightsbridge gathering a shareholder thought he ought to get a better dividend and the Company a better district; at the other meetings the voice of the critic was pitched in a minor key. Three interesting items of information were supplied by the chairman of the Kensington and Knightsbridge Company. The gross earnings per lamp have fallen from 7s. 8d. to 7s. 7d.; the ratio Profit/Gross Income has risen from 0·36 to 0·42, and the Lane-Fox case cost the defendants £6,000.

When the rough balance-sheet of the St. Pancras Vestry's electricity supply venture was first published some weeks ago, we pointed out that the figures neither proved nor disproved the case for the municipalisation of such undertakings. The detailed accounts which are now before us confirm this view. It would be unfair to compare St. Pancras with St. James; on the other hand the Chelsea Company and the St. Pancras concern have one or two points in common. Both supply districts which though dissimilar in character have an equal degree of desirability—or undesirability if one prefers to express the matter in negative terms; and although the St. Pancras area is nominally much larger it is actually much the same size as that covered by the Chelsea Company. Again, whilst the Chelsea Company has expended £81,000, St. Pancras has spent nearly £89,000 of the ratepayers' money; the gross revenues are also much the same being, respectively, £11,000 and £12,500. It was upon "management expenses" and "wages," however, that partisans fastened. The advocates of municipalisation alleged that there would be a considerable saving under the first heading, and opponents retorted that such a saving, if made, would be wiped out by increase under the second heading. So far as the two ventures under consideration are concerned, both prophecies have been partially verified, but the net result favours the municipal vaticination.

In connection with the new Kelvin wattmeter, which is described in another column, it is of interest to consider the suggestion made by Dr. Fleming to supply the current for the shunt coil by means of a little transformer, the primary of which is placed across the mains. When the power to be measured is supplied at a high-pressure, this device seems useful, as it not only saves the expense of a large non-inductive resistance, but also reduces the waste of energy occurring in the instrument. If, for instance, the Kelvin wattmeter described in this issue were employed for measuring the power sent out at 2,000 volts from a central station, it would have to be used in conjunction with a non-inductive resistance of 40,000 ohms, wasting over an eighth of a horse-power. In such cases Dr. Fleming's device could be adopted with advantage. When, however, power is being delivered at low-pressures, it does not seem at all advisable to use a subsidiary transformer in this way, for, although the waste in the instrument could be reduced, the time constant of the circuit containing the shunt coil of the wattmeter would be increased, and the wattmeter would cease to read correctly.

Among the interesting novelties shown by Dr. Fleming at his recent Cantor Lectures before the Society of Arts, were

Hosted by Google

some resistances which promise to be of great value. They were made at his request, by well-known manufacturers of plumbago crucibles, from a mixture of plumbago and Stourbridge clay. The compound was moulded into the form of rods, about a quarter of an inch in diameter and five or six inches in length, and was baked as in the manufacture of crucibles. By using different proportions of clay and of plumbago, the specific resistance can be altered. Very high resistances can be thus obtained without the use of fine and expensive wire, while the temperature coefficient may be reduced to almost nothing, or may be made negative. The curious behaviour of mixed powders noticed by M. Branly and others is said to be absent in these resistances, and they cannot, of course, short circuit by fusion. A half-and-half mixture of plumbago and clay has a resistance more than 4,000 times that of German silver, and such rods will dissipate about 1 watt per square inch.

Cheap and reliable resistances of several hundred ohms would be convenient for a purpose which we venture to suggest with some hesitation. They might be used on ordinary electric supply circuits, instead of Leclanché batteries, for ringing electric bells. The chief advantage would be that they would require no attention, and the serious drawback to electric bells, namely, the drying up or exhaustion of the batteries, would be avoided. Our reluctance in making this suggestion is due to our regret lest, by it, the trade in batteries might suffer; and the thought that few, if any, meters could register the current used for ringing an electric bell. The current, such as it is, would not be used for electric lighting, and would, therefore, come under the cheap rate for power. In the "Hopkinson" system of charging, where a fairly large sum is paid every quarter for the privilege of having 100 volts at disposal at any moment, no compunction need be felt in making such use of the electric mains; but on a plain meter basis, it really seems almost like stealing. And yet when asked to supply light, the companies say: "No, we supply electricity and you can do what you like with it." It is to be feared that our suggestion, if of any value, will be useful only to the consumer, and will be bad for trade. The least we can do, is, by publishing the suggestion, to prevent a patent for the combination of a central station, an electric bell and a high resistance for the purpose hereinbefore set forth, and substantially as herein specified and described.

Royal Institution.—Lord Rayleigh will be unable to deliver his lecture next Saturday afternoon on "Sound and Vibrations" in consequence of illness.

Maidstone.—The Town Council has resolved to obtain information as to the terms upon which a company will carry out their Electric Lighting Order.

Junior Engineering Society.—We are requested to state that the visit of the members of this society on March 2nd is unavoidably postponed to March 9th.

Advance in Mexican Telegraph Rates.—Owing to the continuance of a high rate of exchange, the Mexican Telegraph Company has, states the *Mexican Financier*, of January 28th, advanced its rates, the increased tariff to date from February 1st.

Hammersmith Vestry.—At the last meeting of this Vestry permission was given to the Electric Light Committee to expend £100 in making experiments for the purpose of utilizing the dust and house refuse to produce heat for electric lighting purposes.

The Barry Island Electric Railway.—In deference to a most pronounced expression of public opinion in the district, the Parliamentary Committee of the Barry and Cadoxton Local Board have determined not to offer any opposition to the Barry Railway Company's Bill for an electric railway.

Telegraphic Communication between Germany and the Cameroons.—Dr. Stephan, the German Postmaster-General, on Tuesday received a telegram from Sir John Pender, G.C.M.G., M.P., congratulating him on the establishment of telegraphic communication between Germany and the Cameroons.

Personal.—Sir Henry Trueman Wood, the Secretary of the Royal Commission for the Chicago Exhibition, sailed on Wednesday for America by the "City of Paris," to take charge of the British Section at Chicago. Mr. H. D. Wilkinson, Chief Engineer to the Section, was also a passenger by that vessel.

Society of Engineers.—The first ordinary meeting of this Society was held on February 6, when the premiums awarded for Papers read during the year were presented by the retiring president. A "Society's Premium" was presented to Mr. S. Sellon for his Paper on "Electrical Traction and its Financial Aspects."

The Antwerp Hydro-Electric Scheme.—The Directors of the Compagnie Hydro-Electrique Anversoise announce that notwithstanding the loss the Company has suffered by the death of M. van Rysselberghe, the hydro-electric scheme will go forward under the direction of the best possible technical advisers.

The Groper Microphone.—The Groper Microphone is provided with two diaphragms, one of mica 0·04mm. thick and the other of carbon, a layer of air separating the two. At the back of the carbon disc are several sloping tiers on which are ranged balls of carbon, the front row of each tier resting against the carbon disc.

Electricity in Mines.—The Vicoigne Mines in the Pas-de-Calais are asking for tenders for a somewhat extensive electric mining plant. From a central station, $2\frac{1}{2}$ miles from the mine, current must be supplied to a number of 5-H.P. pumps at the bottom of the mine, to five 6-15 H.P. winding machines, to 12-H.P. hauling machines, and to arc and incandescent lamps.

Cape Town.—The electric lighting of Cape Town, as we have already announced, has fallen into the hands of Messrs. Siemens and Halske. The scheme for street lighting will provide for 30 arc lamps and 400 incandescent lamps, and for private houses about 10,000 lamps of 8 c p. Power will be supplied by water from a specially constructed high level reservoir. Distribution will take place on the 5-wire system with accumulators.

An Electric Acidimeter.—An ingenious apparatus for indicating the progress of fermentation has, says *Industries*, been brought out by Messrs. R. and A. Collette, of Paris. It consists of a pair of battery plates inserted in the fermenting liquid, with a galvanometer connected to them by a pair of wires. As the liquid becomes acid, the deflection of the galvanometer needle increases rapidly. An alarm bell can be worked in connection with the apparatus by a suitable relay.

Train Lighting.—At the last meeting of the Owen's College Engineering Society, Mr. Harry Pollitt, of the Manchester, Sheffield, and Lincolnshire Railway, contributed a Paper on "Train Lighting." Mr. Pollitt referred to the various systems of train lighting by electricity and oil gas, holding that as yet the latter was the best system, as, by only a slight addition to the weight of the carriage, the lamps could be fed for 24 to 36 hours without recharging.

Cable Interruptions.—

	Date of interruption.
Cayenne-Vizeu	September 24, 1892.
St. Thome-Loanda*	February 17, 1893.
Gibraltar-Tangier	February 18, 1893.
Aden-Zanzibar*	February 20, 1893.

* The simultaneous interruption of these cables causes a total stoppage of telegraphic communication with South Africa; the repair of the Aden-Zanzibar Cable is, however, expected within two or three days.

Hosted by Google

Paper for Photometer Screens.—M. Aimé Witz is of opinion, says the *Gas World*, that in photometry the best paper is the French "papier écolier," a soft, dull-surfaced, but smooth and slightly porous, scribbling-paper, and the best stain a spot of olive-oil which has had time to grow old upon the paper, but has neither become yellow or gathered dust. He also remarks that machine-made paper is never the same on both sides, and that it is therefore necessary to have the means of turning the paper round through two right angles, and of examining it on both sides alternately.

The Westinghouse Exhibit at the Chicago Exhibition.—"The Westinghouse plant at the World's Fair promises," says the *Western Electrician*, "to be one of the most attractive features of the exposition, owing to the great size of the engines and dynamos, and the thorough manner in which the work of installation is being done. The great 2,000 H.P. Allis engine, with its fly-wheel 30ft. in diameter, from which will be driven two 10,000 light dynamos in tandem, will occupy a prominent position in the machinery hall, and *is sure to be ever the cynosure of an admiring throng.*"

Glasgow Street Lighting.—At an early hour on Wednesday morning the street arc lamps were switched on for the purpose of testing. As arranged at present, the official inauguration is to take place on Saturday evening. Some 108 arc lamps are to be used; but of these, only 72 have as yet been erected. They are placed alternately on each side of the street at a distance of 160ft. from each other. The lamps are of the Brush Company's make, and are arranged 36 in series, so that the total pressure is about 2,000 volts. When all the lamps are up, the voltage will be 3,000 on each circuit. The iron columns are 17ft. in height; both pillars and lanterns being similar to those used in the City of London.

The St. Louis-Chicago Electric Railway.—According to the *Electrical World* of February 11th, 20 miles of the roadbed of this line have been completed, and contracts for the remainder have been let. The contractors are Bagnall Brothers, of St. Louis, and Givens Brothers, of Memphis, Tenn. Both of these firms are well known and have laid more than 1,800 miles of railroad track for various Western and Southern roads. The contract price is $5,500,000, of which $2,750,000 is to be taken in bonds of the company at par. The time limit of the contract is one year, but it is thought probable that the roadbed will be completed by the autumn, as it is proposed to start work immediately at several different points, and work in both directions.

Power and Lighting Charges at the Chicago Exhibition.—Special illumination can be had at the Chicago Exhibition for 32s. per 16-c.p. light from May 1st to October 31st. The rate for steam power is £8 per horse-power. Those who only require occasional power will be charged 2d. per horse-power per hour. The charges for electric power, exclusive of a fee of £2 or £3 for making connections, will be:—For ¼ H.P. and less, £4; ¼ to ½ H.P., £8; ½ to 1 H.P., £15; 1 to 2 H.P., £14 (per H.P.); 2 to 3 H.P., £12 (per H.P.); more than 3 H.P., £10 (per H.P.). The maximum charge of £4 for ¼ H.P. for six months is at the rate of £32 per H.P. per annum. The minimum charge, £10 per horse power, is at the rate of £20 per horse-power per annum.

The Ventilation of the New York Electric Subways.—It is not, we believe, generally known that the constant explosions which occurred during 1887-1889 in the New York electric subways led to the adoption of a pressure system of ventilation. The plan adopted is to provide by blowers and pipes a pressure in the manholes and ducts greater than the gas pressures in the surrounding earth, and sufficient to renew and change the air in the subways at least once an hour, the subways being kept as air-tight as possible, and the air forced into them being compelled to make its exit through the walls of the manholes or through the walls of the ducts. This system necessitated establishing "blower" stations at different parts of the subways, and there are now in operation twelve Roots blowers in nine different stations.

Aix-la-Chapelle.—Messrs. Schuckert and Co., of Nuremberg, have lately completed the central station at Aix-la-Chapelle. The plant is capable of lighting 20,000 incandescent lamps of 8 c.p. each. There are three Cornish boilers of 1,500 square feet heating surface, by the firm of J. Piedbœuf, of Aix-la-Chapelle. The engines, of which at present two sets are fixed, run at 120 revolutions per minute. They are triple-expansion condensing engines, by C. Kuhn, of Stuttgart; and the dynamos are by Schuckert. There are 140 Tudor cells, with a capacity of 1,610 ampere hours, and capable of discharging at a maximum rate of 483 amperes. There is room left in the building for extension. The cables, manufactured by Messrs. Felten and Guilleaume, of Mülheim-on-Rhine, have a total length of about 40 miles; they are double lead covered and armoured.

Electric Light Box Explosion.—On Wednesday last in the Lord Mayor's Court an action was brought against the Gas Light and Coke Company to recover damages for injuries alleged to have been caused through an explosion of gas. The plaintiff, a warehouseman, said that on October 14th he was in Great Tower-street, standing on a "box" in the pavement which was used for the electric light, when an explosion of gas occurred. The negligence alleged was that there was an escape of gas from the main, and that workmen in digging struck some stones, which emitted sparks, and thus ignited the gas. The defence was that the electric light box became filled with gas, and that the electric light ignited it. It was further stated that the electric light boxes were sources of great danger to the public, because they became receptacles of leakage gas. The jury found for the plaintiff for £40.

M. Moissan's Electric Furnace.—In our issue of December 23, 1892, p. 214, we gave a brief description of a laboratory electric furnace devised by M. Henri Moissan; we gave at the same time a summary of the results obtained by him with this apparatus. Since then M. Moissan has succeeded in making transparent carbon crystals, commonly called diamonds, and as some of our readers may possibly like to try their hand at this fascinating pursuit we give M. Moissan's recipe:—Place about 200 grammes of a mixture of cast-iron and carbonized sugar in a crucible. The crucible should be of carbon and should rest on a bed of magnesia, the whole being contained in a block of lime. After five or six minutes the current is stopped and the crucible and its contents are quickly plunged into cold water. The metal solidifies superficially and the interior mass expanding as it cools becomes subjected to a high pressure, under which the liquid carbon solidifies. On dissolving the nugget with acid a number of microscopic diamond crystals are found.

Earthing Electric Light Circuits.—In an article in *La Lumière Electrique* of February 18th, M. Frank Géraldy discusses the question of "earthing." Theory, he says, indicates that if we wish to earth a conductor it is preferable to earth the negative. With this arrangement, if there is a steady leak, and consequent electrolysis in the vicinity of the electric light circuit, its effects are focussed upon that circuit, whilst in the reverse case water and gas pipes may be attacked, and serious troubles may arise. In either case there is damage and expense, but "it is better to pay one's own little bills than those of other people, who make more fuss and charge more highly." To the contention that since faults are inevitable it is better to frankly ground the system, and thus ensure that incipient faults shall be rapidly developed and localised by blown-out fuses, M. Géraldy replies that accidents seem a rather costly mode of repairing defects of the kind. M Géraldy's advice is that all electrical engineers, whether telegraph, telephone, lighting or traction engineers, should give up the use of earth, as a game not worth the candle.

The Westinghouse Company and the Three-Wire Patent.—At the last meeting of the Brighton Town Council the Lighting Committee reported that, in reply to a letter written on behalf of the Westinghouse Company, they had resolved "that Messrs. Faithfull and Owen be informed that the Corporation have never used and are not using any three-wire system, and that the system they contemplate adopting does not involve the use of two dynamos in series, is thus essentially dissimilar to that of the St. James' and Pall Mall Electric Lighting Company, and is not in any way an infringement of Dr. Hopkinson's Patent." The resolution which immediately succeeded this on the Lighting Committee's proceedings was:—"That the expense incurred in changing over the Pavilion installation from the two-wire to the three-wire system be borne by this

Hosted by Google

Committee." The report was agreed to.—It is understood that there is a probability of an arrangement being come to between he Corporation and the Brighton and Hove Electric Lighting Company, by which the Corporation will be left in undisturbed possession of the electric lighting business in Brighton.

The Westinghouse Separable Lamp.—In a letter to *The Engineer*, Mr. Hiram S. Maxim relates that in the spring of 1881 a consultation was held by the officers and mechanical experts of the United States Electric Lighting Company at New York. The Edison patents were carefully gone into, and Mr. Maxim gave it as his opinion that if the Edison patents were ever sustained it would be on the narrowest kind of a claim, such, for example, as the combination of a slender carbon mounted in a high vacuum, platinum conductors melted into the glass, and with the globe all in one piece. It was decided that Mr. Maxim should make some specimen lamps, and have them ready in case the Edison patents should be eventually sustained on these grounds. He accordingly made some lamps in two pieces exactly, he says, after the manner of the new separable lamp. The specific lamp referred to as the *new* separable lamp was patented by Mr. Maxim in the United States, September 13, 1881, the application being filed April 25, 1881.—Mr. Francis Jehl writes us that in a work by A. Merling (1882), p. 393, it will be found that a glass blower by the name of Böhm describes a lamp similar to the "separable" lamp.

The Liverpool Overhead Railway Electric Signals.—The expenditure of electric energy in working these signals is very small. Each station comprises four signals, each worked with a lowering current of 5 amperes at 40 volts, and with a holding down current of 0·25 amperes at 40 volts. With a three-minutes' service for 20 hours a day, each signal will be lowered 400 times, requiring $400 \times 1 \times 5 = 2000$ ampere-seconds, or (say) 0·5 ampere-hours per signal per day. The entire station with its four signals, each working at 40 volts, would, therefore, require $0{\cdot}5 \times 4 \times 40 = 80$ watt-hours per day, and the total system 1,040 watt-hours, or approximately 1½ H.P. hours per day. This, however, does not include the holding down currents. Assuming each signal to be held down 1½ minutes, it will be down 600 minutes per day, requiring 150 ampere-minutes, or 2·5 ampere-hours, or five times as much as for lowering, that is to say, a total of about 7½ H.P. hours per diem for all the signals. The total expenditure over the whole railway for the whole day, therefore, amounts to about 6¼ kilowatt-hours, which at 8d. per kilowatt-hour costs 4s. 2d., or the cost of a single signalman's wages for the day. Since the kilowatt-hour can be *produced* for much less than 8d., that figure may, perhaps, be taken to include interest, depreciation, &c., about which no mention is made by our contemporary *Engineering*, to whom we are indebted for most of these figures.

Bradford.—The following figures with reference to the working of this station, in addition to those given last week, will be of interest:—The electricity accounts show that the committee have sold electricity of the value of £4,548. 19s. 4d., which is somewhat over £1,000 more than was sold in the corresponding half. Taking the history of the working of the department since its commencement, it will be found that in 1889 there was a loss, including payments on account of sinking fund and interest, of £1,079; in the half-year to June 30, 1890, there was a loss of £732; in the December half a loss of £315; and in the first half of 1891 a loss of £30. For the second half of 1891 there was a profit of £970, for the first half of 1892 there was a profit of £387, and last half-year there was a profit of £1,089. So that from the commencement of the work of the department the whole of the loss resulting in the earlier stages has been extinguished, besides paying interest for sinking fund, and there is a net profit on the undertaking up to date of £289. 15s. 7d. The number of units sold in the last four half-years have been 85,103, and 154,258 in the first and second halves of 1891, and 141,622 and 224,232 in the first and second halves of last year. The numbers of pounds of coal used per unit in the same four periods have been:—16lb. and 12·58lb. for 1891, and 12·5lb. and 10·1lb. for 1892. The cost of coal per unit for the four periods referred to has been, respectively, 0·67d., 0·53d., 0·56d., and 0·42d.

Leicester.—At a special meeting of the Town Council on Monday last the report of the Gas Committee, with reference to electric lighting, came up for consideration. It stated that in July last the Committee had invited tenders; seventeen firms responded and twenty-five schemes were presented. The tender of the Brush Company for £26,977 for an alternate-current transformer sub-station system was recommended for acceptance, and it was suggested that borrowing powers for £50,000 should be sought. The Committee's Report was followed by one from the Gas Engineer, who stated that although the idea of using gas engines naturally presented itself to him he had found on closer investigation that the idea was impracticable, no gas engine being built large and steady enough. The Gas Engineer, in discussing the question of high versus low pressure, comes to the conclusion that the cost of generation is lower in the latter case, but points out that the former system is as a rule adopted in scattered districts bearing no comparison to those usually covered by low-pressure networks. The Gas Engineer is somewhat pessimistic as to the financial outlook of the proposed municipal electric lighting venture. He thinks it probable that the total cost of the unit will be 1s., so that during the first year, even if the maximum charge of 8d. per unit were made, the deficit would no doubt be somewhat heavy. Alderman Lennard in moving the adoption of the report explained the position of affairs at length, stating that the Committee were much impressed with what they saw in Germany, and in consequence it was proposed at Leicester to adopt slow speed compound horizontal direct-coupled engines. After a somewhat heated discussion further consideration of the matter was adjourned for a month, "contractors to be informed that any canvassing of members in the meantime would be a disqualification."

Electric Traction in Queensland.—The Brisbane Metropolitan Tramway Company have petitioned the Governor in Council to postpone the time limited by the Tramways Act for the compulsory purchase of the tramways by the Local Authority from 14 to 25 years. Under the eighty-fourth section of the Tramways Act of 1882 it is provided that 14 years after the completion of the tramway constructed under the provisions of the Act the Municipal Council may purchase the tramway with its appurtenances, subject to any mortgage existing thereon, on giving the company six months' notice of their intention to do so. It is in view of their intention to substitute electricity for horse-power that the Company have, under the 12th section of the Tramways Act of 1882 Amendment Act, presented a petition to the Governor in Council for an extension of time. The petition has been acceded to. Under Clause 3 of the Tramways Amending Act the Governor in Council has power to impose conditions with respect to the position of the wires of electric tramways so as not to interfere with the working of the telegraph and telephone wires. The following conditions, which are said to be based on those in force in the United States, have been recommended by the Postmaster-General, and have been approved:—1. Poles to be of suitable dimensions, and to be not less than 25ft. in height, and so placed as not to interfere with telegraph poles or wires. 2. Poles to be distant from one another not more than 130ft. 3. Supporting wires to be not less than 23ft. in height above the surface of the earth. 4. Conducting and trolley wires to be not less than 22ft. in height above the surface of the earth. 5. Conducting and trolley wires to be insulated in a suitable manner, to the satisfaction of the Postmaster-General, and so as to prevent the current being conveyed to the non-conducting poles or wires. 6. Proper precautions must be observed, to the satisfaction of the Postmaster-General, to prevent the falling of wires or cords; also for protecting the trolley wires by steel guard wires running parallel to them, not less than 6in. away, as a precaution against accident from the falling of telegraph, telephone, or other wires. 7. Special arrangements, approved by the Postmaster-General, to be made at crossings. 8. *A second or return wire to be provided instead of using the earth as a return circuit.* 9. The conducting wire to be carried at the opposite side of the respective streets or roads to that on which the telegraph or telephone lines are placed. 10. Each section to be provided with automatic devices for switching off at power stations.

ELECTROMAGNETIC THEORY.—XLIV.

BY OLIVER HEAVISIDE.

(*Continued from page 353.*)

§ **185.** For this reason, a perfectly conducting mass exposed to electromagnetic radiation in ether cannot be heated thereby, for heating would imply the absorption of energy. If, then, the law (whose existence has long been suspected) that metals tend to become perfect conductors when their temperature is sufficiently lowered, were absolutely true, it would follow that a metal, if once brought to zero temperature, would remain there, provided its only source of heat-energy be electromagnetic vibrations. At the same time it is conceivable, and, indeed, inevitable, that it should receive energy from them to some extent in another way, viz., by the electromagnetic stress producing motion in bulk, even though the establishment of irregular molecular motions be prevented.

Similarly, we should expect that a metal which obeys the law approximately would show very small absorptive power for radiation at very low temperatures. This refers to the reception of the energy of true radiation in ether—that is, in vacuo. A body may become heated in other ways, by the impacts of air particles, for example, if air be present. Prof. Dewar's late experiments are suggestive in this respect, but it is too soon to draw conclusions from partially-published experiments.

But even as regards strongly absorptive bodies, the perfectly black body of the thermal philosophers, for example, we may expect a similar diminution of absorptive and emissive power with fall of temperature. Stefan's law of radiation asserts that the emissivity varies as the fourth power of the absolute temperature. Since, however, in deriving this law from electromagnetic principles, as has been recently done by B. Galitzine, we seemingly require to invoke the aid of reversible cycles and the second law of thermodynamics, whose range of application is sometimes open to question, we may well be excused from an overhasty acceptance of the law as the expression of absolute fact. The second law of thermodynamics itself needs to be established from electromagnetic principles, assisted by the laws of averages, so that we may come to see more clearly the validity of its application, and obtain more distinct notions of the inner meaning of temperature.

§ **186.** As before said, a perfectly conducting screen enclosing a dielectric region supporting electromagnetic disturbances, keeps in their energy, which remains in the electric and magnetic forms, and if there be no sources of energy present, the total energy remains constant. Some interesting questions arise regarding the subsequent history of the electromagnetic disturbances, when left to themselves, subject to the obstructing and reflecting action of the screen.

In certain cases the initial state will continue absolutely unchanged; for example, when it is the steady state due to electrification, or associated therewith. Similarly as regards an initially steady state of magnetic force, that, for instance, associated with a linear current (without resistance) in the enclosed region. Again, in other cases, although the subsequent history of an initial state may be one of constant change, yet there will be regular recurrence of a series of states; as when a periodic state of vibration persists without any tendency to degrade. It is sufficient to mention the very rudimentary case of a plane wave running to and fro between parallel plane reflecting boundaries, without the slightest tendency to change the type of the vibrations. We see from these examples, which may be multiplied, that there is no necessary tendency for the initial state, even when vibratory, to break up and fritter down into irregular vibrations. Nevertheless, there does appear to be a general tendency to this effect, when the initial states are not so artfully selected as to prevent it happening. Even when we start with some quite simple type of electromagnetic disturbance, the general effect of the repeated reflections from the boundary (especially when of irregular form) and the crossing of waves is to convert the initial simplicity into a highly complex and irregular state of vibration throughout the whole region. This cannot happen universally, as we have seen, and therefore a general proof of conversion from any initial state to irregularity cannot be given; but there can be little doubt as to the usual possibility of the phenomenon. Especially will this be the case if the initial state be itself of an irregular type, such as that due to ordinary radiation from matter, when it is tolerably clear that the irregularity will persist, and become more complete.

Let us, then, assume that we have got the medium within our screen into this state in its extreme form, without enquiry into the intermediate stages. Then the very irregularity gives rise to a regularity of a new kind, the regularity of averages. The total energy, which is a constant quantity, will be half electric and half magnetic, and will be uniformly spread throughout the enclosure, so that the energy density (or energy per unit volume) is constant. As regards the displacement and the induction, they take all directions in turn at any one spot, quite irregularly, but so that their time-averages show no directional preference. Similarly, the flux of energy, which is a definite quantity at a given moment at a fixed spot, is constantly changing in amount and direction. But in virtue of the constancy of the mean density and the preservation of the normal state by constant exchanges of energy, there is a definite mean energy flux to be obtained by averaging results. This mean flux expresses the flux of energy per second across a unit area anywhere situated within the enclosure.

To estimate its amount, let the mean density of the energy be U. This is to include both kinds. Now fix attention upon a unit area, A, fixed in position anywhere within the enclosure, and consider the flux of energy through it under different circumstances. First of all, if the energy all moved the same way at the same speed v (that of propagation), as in simple plane progressive waves, and the direction of its motion were perpendicular to the fixed unit area A, then the energy passing through it would belong to a ray (or bundle of rays) of unit section, and the energy flux would be Uv simply. This is the maximum. But this is impossible, because energy would accumulate on one side of A at the expense of the other. The next approximation, to prevent the accumulation, is to let half the energy go one way and half the other; still, however, in the same line. This brings us down to $\frac{1}{2}Uv$. To go further, we must take all possible directions of motion into account. The original ray conveying Uv must assume all directions in turn, and the mean value of the flux through A must be reckoned. Now, if the ray of unit section be turned round so as to make an angle θ with the normal to A, the effective section of the ray is reduced from 1 to $\cos\theta$; that is, $\cos\theta$ is the fractional part of the ray which sends its energy through A, through which the flux per second is therefore $Uv\cos\theta$, due to the ray at inclination θ. The true flux through the area A is therefore the mean value of $Uv\cos\theta$ for all directions in space assumed by the ray. Now the mean value of $\cos\theta$ for a complete sphere is zero, and therefore the mean flux through A is zero. This is right, as it asserts that as much goes through one way as the other. To obtain the amount going either way we must average over a hemisphere only. The mean value of $\cos\theta$ is then $\frac{1}{2}$. But we are only concerned with half the total energy, or $\frac{1}{2}U$, when we are confined to one hemisphere. Consequently we have

$$W = \tfrac{1}{4}Uv, \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad (4)$$

to express the flux of energy W per second each way through any unit area in the enclosure.

Another way of getting this result, which is, however, essentially the same, is to divide the original ray of unit section along which the flux is Uv into a very great number n of equal rays of unit section, each conveying $1/n$ part of the same, and placed at such inclinations to the normal to A that no direction in space is favoured. This amounts to dividing the surface of a sphere whose centre is that of the area A into n equal parts, the centre of every one of which defines the position of one of the n rays. Any ray now sends $(Uv/n)\cos\theta$ through A per second. Now sum this up over the whole hemisphere and the result is W. In the limit, when n is infinitely great, we have

$$W = \int_0^{2\pi}\int_0^{\frac{\pi}{2}} \frac{Uv\cos\theta}{4\pi}\sin\theta\, d\phi d\theta = \tfrac{1}{4}Uv, \quad . \quad . \quad (5)$$

as before. The 4π divisor in the integral is not the unspeakable 4π of the B.A. units. It is the area of the sphere of unit

Hosted by Google

radius, whilst the other factor $\sin\theta\, d\theta d\phi$ is the area of an element of the sphere.

As this is an important fundamental result in radiation, it is desirable to establish it as generally and simply, and with as much definiteness of meaning as possible. Bartoli made it only $\frac{1}{2}Uv$ (apart from electromagnetic considerations, which are, however, only accidentally involved). On the other hand Galitzine makes it $\frac{1}{4}Uv$ by considering a special case, viz., that of a cylindrical enclosure with flat ends, one of which is a radiant source (perfectly black) at constant temperature, whilst the other end and the round surface are perfectly reflecting. It would appear, however, from the above method, that the result is general, and is independent of sources of heat, and of the emissivity and temperature. Since we made no use of the screen after introducing it to keep in the radiation, it may be dispensed with, provided the stationary condition be still maintained. Thus, if a portion of the screen be made "perfectly black," maintained at constant temperature, the quantity W, which represents the amount of heat falling upon it per unit area per second, is completely absorbed by it. But this is perfectly compensated by the emission from the black surface of an equal amount of heat. So $\frac{1}{4}Uv$ measures the total emissivity under the circumstances.

§ 187. Another important fundamental quantity is the mean pressure of radiation. In a simple ray the electric and magnetic stresses unite to form a pressure U along the ray, with no pressure or tension in lines perpendicular to the ray, that is, in the plane of the wave, as described in § 86. But when the radiation is balanced as in the last paragraph, there is no directional preference, and the pressure is all ways in turn, and therefore on the average, simulates a hydrostatic pressure. Its value may be readily estimated in a manner similar to that employed above concerning the mean flux of energy. When we make the energy U go all one way in a ray of unit section through the area A situated anywhere, the pressure in the ray is U, and this is the pressure on A if the ray is perpendicular to A. But when the ray is inclined to the normal to A at an angle θ, only the fraction $\cos\theta$ of the ray is concerned in the action upon A. Furthermore, the line of pressure is inclined to the normal to A at an angle θ, so that the effective normal pressure is still further reduced by the factor $\cos\theta$ a second time. The pressure on A is therefore only $U\cos^2\theta$. This must now be averaged for all directions in space that we may give to the ray, without preference. Now the mean value of $\cos^2\theta$ for the complete sphere is $\frac{1}{3}$. So the pressure, say p, is given by

$$p = \tfrac{1}{3}U. \qquad (6)$$

Notice particularly that we take the mean for the complete sphere, not merely for the hemisphere as in the former calculation. The reason is that whether a ray goes through A from right to left or from left to right, the pressure is the same: so both ways have to be reckoned.

Or, we may divide the original ray in which the pressure is U into a great number n of rays also of unit section, in each of which the pressure is U/n. Let the axes of these rays be defined by the middle points of n small equal areas into which we may divide the surface of a sphere, and sum up the normal pressures on A. We obtain, in the limit,

$$p = \int_0^{2\pi}\int_0^{\pi} \frac{Uv\cos^2\theta}{4\pi}\sin\theta\, d\phi d\theta = \tfrac{1}{3}Uv \quad . \quad . \quad (7)$$

This result was given by Boltzmann some years ago, and Galitzine confirms it for the special case of his straight cylinder with a radiant surface at one end. By the above method we see that the result is general, resulting from the uniformity of radiation in all directions, as the previous formula for the mean flux of energy did.

§ 188. This pressure p is not only the mean pressure throughout the enclosure, but also the the pressure on its envelope, which exerts an equal back pressure. If it move, then work is done by or against the enclosed radiation through the agency of its pressure, and the enclosure loses or gains energy to an equal extent. Observe that the idea of temperature does not enter explicitly when the boundary of the enclosure is of ideal perfectly reflecting material. But when it, or a part of it, is made absorptive and emissive, the physics of the matter becomes far more difficult and to some extent dubious. The notion of temperature comes in, and with it the second law of thermodynamics. Assuming its full applicability, Stefan's law follows easily enough, as Galitzine has shown. Let the enclosure be a cylinder of unit section with two pistons A and B. Let A be fixed, and be a perfectly black body, whilst B is moveable to and from A and is a perfect reflector, as is also the round cylinder.

Now start with B close to A; the volume of the enclosure is then nil. Draw B very slowly away from A through the distance h, keeping A at constant temperature t all the time, and then stop it. During this operation the source A keeps the enclosure filled with energy to density U, and pressure p, corresponding to the temperature t at which A is maintained. The pressure p does the external work ph. Besides that, there is energy Uh in the enclosure at the end of the operation. Their sum is therefore the heat lost by A (excess of heat emitted by A into the enclosure over that returned to A). Say

$$H = (U+p)h \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad (8)$$

Now we know p in terms of U, so that we have, by (6),

$$H = \tfrac{4}{3}Uh. \quad . \quad . \quad . \quad , \quad . \quad (9)$$

Now, B being fixed, let the cylinder cool down to zero temperature. The whole of the energy Uh in the enclosure goes out through A. Lastly, push B back to A without working, and then raise A to temperature t. A cycle is then completed. Applying the second law, we have

$$\frac{H}{t} = \int_0^t \frac{1}{t}\frac{dH}{dt}dt, \quad . \quad . \quad . \quad . \quad . \quad (10)$$

where H is as before, and dH is an element of the heat lost in the cooling process. On the left side put $(U+p)h$ or $\frac{4}{3}Uh$ for H, because external work was done in the first operation. On the right side leave out the p term, because during the cooling B was fixed. So we get

$$\frac{\frac{4}{3}U}{t} = \int_0^t \frac{1}{t}\frac{dU}{dt}\,dt, \quad . \quad . \quad . \quad . \quad (11)$$

by omitting the factor h. Differentiate with respect to t, and we get

$$\frac{dU}{dt} = \frac{4U}{t}, \quad . \quad . \quad . \quad . \quad . \quad . \quad (12)$$

from which we conclude that U, and, therefore, also p and W, vary as the fourth power of the temperature, the result above mentioned as applied to the emissivity W.

We tacitly assume that the ether is able to escape freely from the cylinder through its envelope, or else that it is freely compressible, without resistance. This difficulty in connexion with the ether is a very old one.

(To be continued.)

ON THE DETERMINATION OF THE INSULATION RESISTANCE AND OF FAULTS IN ELECTRICAL PLANTS DURING THE WORKING.

BY DR. O. FROELICH.

(Concluded from page 442.)

System of Two Conductors.—In this system only one bridge test can be taken. If a is connected to conductor 1, b to conductor 2, it follows:—

$$(7g.)\quad \frac{k_1}{K} = \frac{b}{a+b} \text{ and } \frac{k_2}{K} = \frac{a}{a+b}$$

In this system the single faults of the two conductors can also be determined by measuring the insulation of the whole system and the absolute potential of one conductor.

In general it is useful to take these tests during the day, because then the resistance m of the machines can be neglected in proportion to the resistance l of the lamps between two

Hosted by Google

neighbouring conductors; then the formulas are the following simple ones:—

System of Five Conductors.—

$$(7h.)\quad k_1/K = 1/8(1 + 4\,\mu_{51} - 3\,\mu_{12}),$$
$$k_2/K = 1/8(2 + 3\,\mu_{12} - 3\,\mu_{34}),$$
$$k_3/K = 1/8(2 + 3\,\mu_{23} - 3\,\mu_{45},)$$
$$k_4/K = 1/8(2 + 3\,\mu_{34} - 3\,\mu_{45}),$$
$$k_5/K = 1/8(1 + 3\,\mu_{45} - 4\,\mu_{51}).$$

System of Three Conductors.—

$$(7i.)\quad k_1/K = 1/4(1 + 2\,\mu_{31} - \mu_{12}),$$
$$k_2/K = 1/4(2 + \mu_{12} - \mu_{23}),$$
$$k_3/K = 1/4(1 + \mu_{23} - 2\,\mu_{31}).$$

Determination of the Position of One Heavy Fault in a Central Station.

Method 8a. (Fig. 8a. Testing in the streets.)—When a heavy fault developes in a central station, the main conductor, to which the fault is attached, must be determined by methods 5 or 6; then, when, by any means, the region of the fault is known, we can determine its exact position in the following way. Between two neighbouring accessible points of the conductors two lines $l_1\,l_1$ and $l_2\,l_2$ are laid in the street and connected to the faulty conductor (see Fig. 8a); in l_1 a galvanometer or a telephone of low resistance is inserted, in l_2 a wire bridge $a\,b$; from the moveable contact a branch B containing a contact-breaker and some accumulators or resistance is connected to earth. The place of the contact is sought, for which

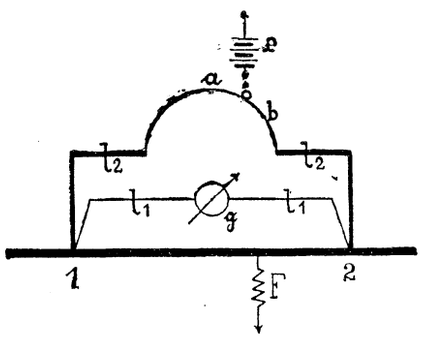

Fig. 8a.

the current in the galvanometer or the telephone does not change by opening and closing B. If the fault F lies between the points 1 and 2, we can measure and can determine the position of the fault by the known rule. If the fault lies to the left of 1, the place of the contact, which nearly gives a balance, is in the left corner; it is in the right corner, if the fault lies to the right of 1. Thus, if no determination can be made, remove the lines and instruments in the given direction, and take a new test between two other accessible points. The operation is repeated, until the determination is made; then the lamps on the faulty part of the main conductor are removed in order to take the last and exact test. Instead of the lines l_1 and l_2 we can use the small wires, which are usually laid by the main conductors for testing purposes (testing wires).

Method 8b. (Fig. 8b. Tests from the station.)—The method just described, and other ones, Messrs. Siemens and Halske, in April, 1892, proposed to patent. On September 30, 1892, Dr. Hiecke, of Vienna, described a method by which the localisation of a heavy fault could be obtained by tests from the station; for this method two feeding conductors must be taken off the machines. Between the feeders H_1 and H_2 insulated at the station, a low pressure machine, or a battery of accumulators with a contact breaker A is inserted; between the testing wires P_1 and P_2 the wire bridge $\alpha\,\beta$. A mirror galvanometer and a battery B for compensating purpose are placed between the moveable contact and earth. The battery is adjusted so that the galvanometer has no current. When the moveable contact has got the right place, the galvanometer must show no deflection when the contact breaker A is open or closed. This test is repeated with different feeding conductors; from the results the position of the fault is obtained by a special calculation.

If we compare this method to Method 8a, we see that the principle is the same. In 8b the diagonal branches of the bridge are interchanged, the current in the galvanometer is brought to zero and the telephone is not mentioned. The main difference of the two methods consists in that Dr. Hiecke takes the tests at the station by means of some changes in the main connections, and we test in the streets almost without change in the main connections.

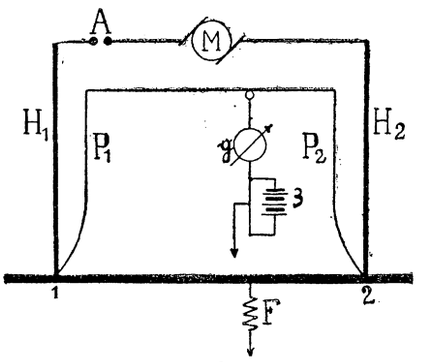

Fig. 8b.

If we adopt Dr. Hiecke's idea and adapt to Method 8a, we come to the Method 8c (Fig. 8c). The bridge wire lies between the detached feeders $H_1\,H_2$, the galvanometer or telephone between the testing wires $P_1\,P_2$, the accumulators with contact breaker between the moveable contact and earth. If the tele phone is used we close and break the contact by turning a suitable contact wheel by hand or by an electric motor.

Testing Arrangement for Central Stations.

The methods described above have been tried on a small system of three conductors, and several instruments have been constructed for the purpose. The instruments, which are partly necessary, partly useful, are a wire bridge, a bridge composed of bobbins, with a rotating handle, telephones of different resistances, a hand contact wheel, a contact wheel driven by an electric motor, a mirror galvanometer, which can easily be transported, put up and used in any place, voltmeters of higher accuracy than usual, but available in engine-rooms, different resistances. In the mirror galvanometer it is very useful to adopt the magnetic compensation mentioned above, and to put mirror, magnets, and suspension fibres into water, by which device a good damping is obtained; thus, a fixing

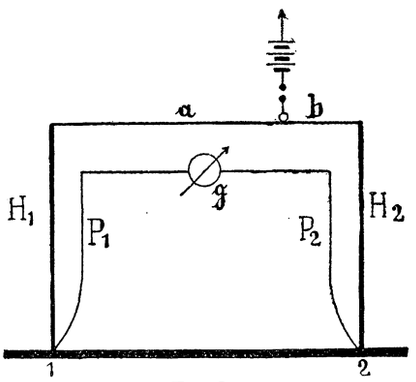

Fig. 8c.

arrangement for the transport can be omitted, and the putting up is so easy that screws for adjusting the level position are not necessary. The deflections are read as usual by aid of a petroleum lamp, but can be taken in full daylight; the box containing the galvanometer and its belongings is short and easily transportable.

Beside the described tests it is useful during the working of the plant to measure the potentials at as many points as possible of the same main conductor by a mirror galvanometer

Hosted by Google

and testing wires from the station in the day and night; this is a good preparation for the appearance of a heavy fault. For, if the fault develops, the fault and its surroundings show low potentials. It is true, that other points of the same conductor can also have low potentials in consequence of an irregular distribution of the current; but the points of low potential of the latter sort change during the day and during the night, whereas the potential of the faulty place always remains low. So these tests will be useful for determining the region of the fault.

The tests which, in a central station, are partly necessary, partly useful, and can be taken during the working, are the following:—

(1) Continuous observation of the insulation (Method 3).

(2) Determination of the general insulation (Methods 1, 2, 3, and 4).

(3) Determination of the faulty main conductor (Methods 5 and 6).

(4) Determination of the fault of every main conductor (Method 7).

(5) Measurement of the pressure on the same main conductor with different loads (day and night).

(6) Determination of the place of a heavy fault by tests from the station (Methods 8b, 8c).

(7) Exact determination of the place of a heavy fault by tests in the street (Method 8a).

I suppose that the development of testing in central stations will take the same course as it was with deep-sea cables. At first, tests were despised as "scientific humbug" and quite omitted, then testing was introduced for determining heavy faults, and at last, when it became plain that testing was useful, it was made use of as much as possible. Most of the methods described are directly appliable to alternate currents; but I hope to treat of that in a special article.

LATITUDE AND THE LOAD-FACTOR.

BY E. TREMLETT CARTER, F.R.A.S.

When Greenland's icy mountains sparkle in electric light, and arc lamps are dotted along the rugged lines of India's coral strand, a comparison of a year's working would show that the load-factor of a supply station and the conditions of economical working are affected by the latitude and other astronomical functions of the area of supply. Owing to the inclination of the earth's axis to the plane of the ecliptic—which, by-the-bye, Milton tells us was produced as a punishment for man's sin—the distribution of darkness and sunlight over the face of the globe is by no means as simple as an electrical engineer might desire. This inclination causes the interval between sunset and sunrise to vary harmonically from day to day throughout the year; producing, for a plain man, the delights of season, and for the electrical engineer the harassing differences between the five per cent. load-factor of July and the 25 per cent. load-factor of December. Nor is this all; for the same inclination of the earth's axis produces a different distribution of day and night for each latitude. Away up within the Arctic Circle, or in its almost unexplored austral counterpart, there are periods of uninterrupted darkness surpassing the achievements of our best London fogs. At Hammerfest, in Norway, four degrees within the Circle, where there is a small electric light station driven by a mountain torrent, the yearly programme includes a night of 66 days duration and a "day" of equal period; while at the North Pole itself the year comprises a six months day and a six months night. If we should sail to the tropics we should find an equality in the days and nights throughout the year which becomes more perfect as the Equator is approached. Within one degree of the line the variation in the length of night is not more than 12 minutes between the two solstices at the rainy and dry seasons.

One term, then, in the mathematical equation to the load-factor of any station will be a trigonometrical function of the latitude of the area of supply. In the *Nautical Almanac* the data for calculating the length of night or day at any latitude and at any time of the year are to be found, which raises the curious question as to whether this admirable compilation should not be found on the shelves of a consulting electrician. These data, worked out, may be plotted in the form of a Cartesian curve, similar to that in "*The Electrician* Electrical Trades' Directory and Handbook for 1893," page 190. In order to show the extent of this effect, the author has plotted curves of these quantities for St. Petersburg at latitude 59deg. 52min., and Singapore, latitude 1deg. 20min.

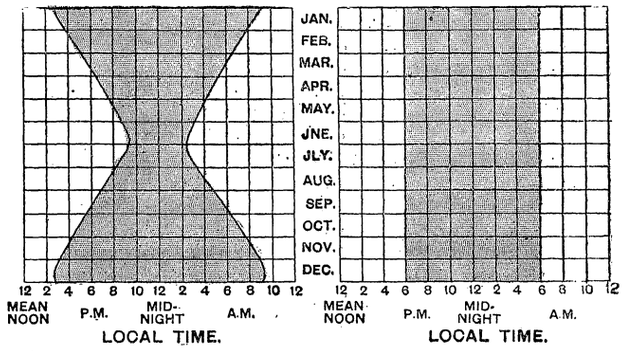

FIG. 1.—St. Petersburg, Lat. 59° 52′ N. FIG. 2.—Singapore, Lat. 1° 20′ N.

These present a very wide variation, but not so wide as would have occurred by comparing the latter with a point within the Arctic Circle. The shaded area represents the time when the sun is below the sea-level horizon. Ordinates are drawn for the hours of the day, reckoning local mean solar time; and abscissæ for the months of the year. Thus, everything is reduced to normal calendar.

Lest it should be supposed that the influence with which we are now dealing is one of importance only where points widely separated on the surface of the globe are taken, two similar curves have been plotted for points within the United Kingdom. Aberdeen and Falmouth are just 7deg. of latitude apart; and the differences in the distribution of darkness are shown by Figs. 3 and 4. At Falmouth the difference between the shortest and longest nights is 8h. 20min.; while at Aberdeen the difference is 11h. 12min. The percentage variation on the shortest night is—in Falmouth 106 per cent., and in Aberdeen 175 per cent.

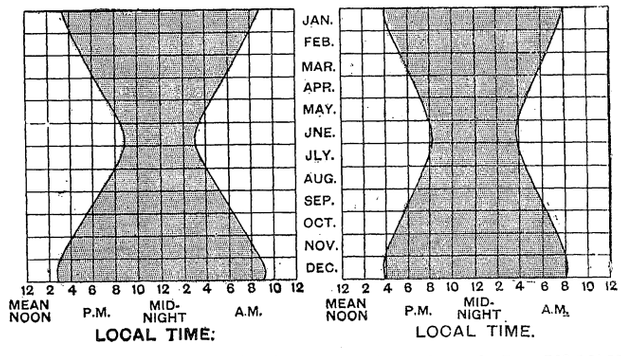

FIG. 3.—Aberdeen, Lat. 57° 10′ N. FIG. 4.—Falmouth, Lat. 50° 10′ N.

Latitude has an indirect influence, in the effects of climate on the refraction and transparency of the air. Where there is a humid atmosphere, as in our "temperate" climate, there is, besides the comforting liability to fog, a general refraction of the sunlight which delays the beginning and hastens the ending of darkness. The apparent time of sunset is later than the actual time, and the limb of the sun may be seen above the horizon before he is actually risen. Humid atmospheres also reflect and refract the lingering rays of sunlight, producing the gradual disappearance of day which is called twilight. This phenomenon is almost completely absent in a tropical atmosphere; and, in those climates where the day is constant in

Hosted by Google

length, it also passes swiftly into the blackness of night. At Hong Kong all the lights must be switched on within five minutes of sunset, for it is as dark as midnight by then. Twilight renders it easier to start numerous machines at a station, as they may be started in slow succession; but it leads the consumer to be indecisive in turning on lamps, and thus makes the load creep up gradually instead of running up to a maximum sharply. In the latter respect twilight has a tendency to reduce the load-factor of the station all the year round. Within the Arctic Circle the irregularity of the nights would be compensated by the long runs which the machinery would have in the polar night, and by the reduced cost of such a station during the long polar day. It is true that the Aurora Borealis lightens the gloom by its occasional brilliance; but the uncertainty of the display would render it impossible to save much of the station expense on that account, while a first-class Aurora might, perhaps, induce the economical Scandinavian to turn his lamps off.

The moon, too, has her influence on the load-factor; especially in those climates where the dryness of the air renders her light of certain and practical value. In many of the tropical and colonial towns street lighting is only contracted for for about a fortnight in each lunar month; during the other fortnight the moonlight being sufficient to light the streets. Whether lamps must be run during a total eclipse, and whether this item has been taken into account in the estimate, is not clear; but it is evident that both solar and lunar eclipses may play some part in the yearly work of the supply company, and would be a matter of gain as regards private house lighting; though it is possible that, as with Mark Twain's hotel-keeper, "a succession of total eclipses might ruin the business"—as regards street lighting. Perhaps eclipses are too infrequent to be worth considering in most places; and it is certain that, in London, latitude, twilight, moonlight and eclipses, all put together, are not equal in importance to one or too big London fogs.

NEW KELVIN ENGINE-ROOM WATTMETER.

The latest invention of Lord Kelvin is an engine-room wattmeter. One of these instruments was exhibited by Dr. Fleming at his Cantor lectures at the Society of Arts last

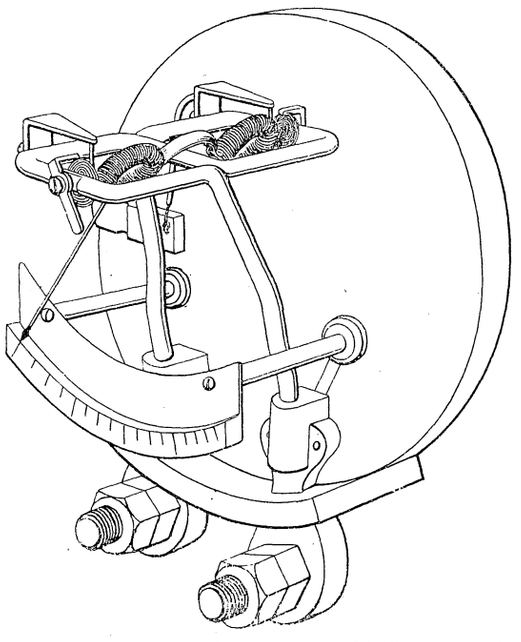

Fig. 1.—General View of Instrument, with Case removed.

week. The interior is shown in Fig. 1. It has a main circuit formed of a double rectangle of copper rod having sufficient area to carry 200 amperes, and a shunt circuit with two fine wire coils astatically arranged. The main coil is mounted on a slate back so that the rectangles are horizontal. The shunt coils are mounted on a light but strong aluminium frame in the manner shown in Fig. 2. One end of this frame has a circular knife-edged hole fixed to it, and the other end has a straight knife-edge. These two knife-edges rest on two phosphor-bronze hooks attached by insulating supports to the outside ends of the double rectangle. By this method of suspension complete freedom from friction is obtained, while the moveable system is kept in a definite position without end guides.

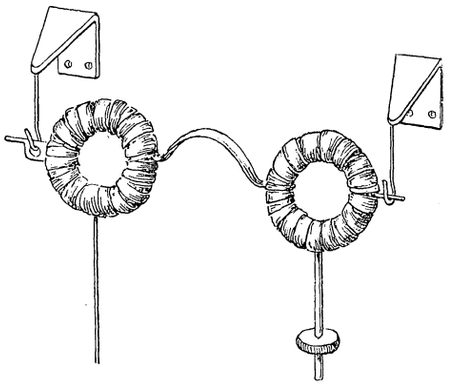

Fig. 2.—View of Fine Wire Shunt Coils, showing Details of Suspension. Controlling Springs removed.

Each fine wire coil has about 1,000 turns of insulated wire, and its resistance is about 100 ohms. The current is conducted in and out from the moveable system by two flat palladium spiral springs which also supply the restoring force for governing the sensibility of the instrument. Not more than 1-20th of an ampere is allowed to pass through the fine wire circuit, and in order to regulate this, a large non-inductive resistance is rolled on the case of the instrument which offers a large cooling surface. The scale has nearly uniform divisions, and is graduated to read directly in watts or kilo-watts as required. The capacity of this instrument is 200 amperes, the volts being immaterial.

MEETINGS OF SCIENTIFIC SOCIETIES, &c.

(TO-DAY) FRIDAY, February 24th.

PHYSICAL SOCIETY.

5 p.m. Papers to be read: (1) "A Handy Focometer," by Prof. J. D. Everett; (2) "Plane and Spherical Sound Waves," by Dr. C. V. Burton; (3) "Motion of a Perforated Solid in a Fluid," by G. H. Bryan, M.A.

INSTITUTION OF CIVIL ENGINEERS.

7.30 p.m. Students' Meeting. Paper to be read: "On the Methods usually adopted in Devon and Cornwall for Dressing China-Clay and Tin-Ore," by R. Hansford Worth, Stud.Inst.C.E.

ELECTRO-HARMONIC SOCIETY.

8 p.m. Ladies' Night. Concert at St. James' Hall Restaurant.

ROYAL INSTITUTION.

9 p.m. Evening Discourse: "Electrical Railways," by Dr. Edward Hopkinson, M.A.

TUESDAY, February 28th.

INSTITUTION OF CIVIL ENGINEERS.

8 p.m. Ordinary Meeting. Resumed discussion upon the Paper "On Electrical Railways," by Dr. Edward Hopkinson. Paper to be read, time permitting: "On Plant for Harbour and Sea-Works," by Walter Pitt, M.Inst.C.E.

WEDNESDAY, March 1st.

INSTITUTION OF CIVIL ENGINEERS.

4 p.m. Students' Visit to the Houses of Parliament, to inspect the Clock-Tower and the Ventilating and Lighting Arrangements.

SOCIETY OF ARTS.

8 p.m. Ordinary Meeting. Paper to be read: "Tele-Photography," by Thomas R. Dallmeyer.

THURSDAY, March 2nd.

CHEMICAL SOCIETY.

8 p.m. Ordinary Meeting. Papers to be read.

FRIDAY, March 3rd.

OLD STUDENTS' ASSOCIATION.

8 p.m. Meeting at the Central Institution. Lecture "Mountaincraft," by Clinton T. Dent (illustrated by lantern views).

THE TRANSMISSION OF POWER FROM CENTRAL STATIONS.

On Friday last Prof. UNWIN concluded his course of six Howard Lectures before the Society of Arts. We have heard and read about electrical transmission of power until the subject has become wearisome. The ingenuity of the inventors of the *drehstrom* system has been equalled only by the boldness of those who have proposed schemes for distributing power from the coal fields to the towns, and it is quite time that the tendency to overrate the advantages of electrical transmission of power and to lose sight of commercial considerations should receive a check. Prof. UNWIN's confession, on opening this course of lectures, that he was not an electrician, so far from placing him at any disadvantage, greatly enhanced the value of the comparisons which he made, and even if electrical transmission had come out rather badly at his hands there are plenty of enthusiasts who would do their best to neutralise the possible effect of his decision by any amount of talk. But Prof. UNWIN did not attempt to recommend one system of distribution rather than another, even for special purposes. The importance of a comparison between the rival methods has led us to devote more space to a report of these lectures, and thus to place more non-electrical matter before our readers, than is usual.

One of the most interesting and original features of this series of lectures was the recognition of a definite money

Hosted by Google

value for different systems of storage. A reservoir of power, whether it be a mountain lake, or a fly-wheel may be considered from three points of view—the first cost, taking only the storage capacity into account; the first cost, taking the discharge rate into account; and, lastly, the annual charge to cover interest and maintenance. The first of these is the prime cost of a reservoir of energy of a given capacity, the cost being reckoned at per horse-power-hour of the whole energy stored; the second is the prime cost of a reservoir, the cost being reckoned at per horse-power discharged; and the third simply is energy in horse-power-years. As an illustration of the difference between the first two, we may take the extreme case of a good Leclanché battery. A single cell discharging through 10 ohms for three weeks with a mean current of 85 milliamperes, will do about one-twentieth of a horse-power-hour. But it would be absurd to call 20 such cells a two horse-power battery; it would only be a two horse-power-hour battery. A cell giving 746 amperes at two volts would be a two horse-power cell. Prof. UNWIN's estimate of 5s. 6d. as the cost of a gas holder per horse-power-hour stored must be taken with caution, and in all other cases the rate of discharge must be carefully considered in connection with the cost of a reservoir. Two extreme figures were given for the cost of secondary batteries, differing, indeed, so widely as to be of small value. These, together with other prices given by Prof. UNWIN, we give in the form of a table, making no attempt in this or in the succeeding table to add in any way to the original figures as given in the lectures.

Cost of Storage.

	H.P. Hour Stored.	H.P. Discharged.	Annual Charge.
	£ s. d.	£ s. d.	£ s. d.
Gas Holder	0 5 6	6 0 0	0 10 0
Battery, Frankfort	23 0 0	78 0 0	15 6 0
„ Epstein	8 0 0	20 0 0	—
Druitt Halpin (condensing)	1 13 0	—	—
„ (non-condensing)	2 5 0	—	—
Geneva reservoir	2 4 0	—	0 3 0

Prof. UNWIN did not make any direct comparison between Mr. DRUITT HALPIN's thermal storage scheme and secondary batteries for obvious reasons, but they appear together in the table. In the use of secondary batteries an attempt is made to store the actual thing produced by a supply station, but it seems that when they do little more than the air-vessel of a water-works they are most satisfactory. The hot water storage stops a long way short of this, and is practically a storage of steam in no way relieving the dynamos and engines from the irregularities of load which so seriously affect their efficiency.

The following table of costs of power is compiled directly from the Howard lectures, with no change save conversion of dollars into English money, in round figures.

Cost of Power per Horse-power-year.

Water Power.	£ s.	*Hydraulic Supply.*	£ s.
United States, N.W.	2 5 – 2 10	Hull	104 0 – 83 0
„ New Jersey	12 0 – 16 0	London	175 0 – 35 0
„ Holyoke	4 15	*Compressed Air.*	
St. Lawrence	4 7	Paris (3,000 hrs.)	6 5
Switzerland (average)	6 0	*Steam Supply.*	
Geneva	8 0	New York, steam (3,000 hrs.)	12 10 – 7 10
Schaffhausen	4 16 – 6 0	*Electric Supply.*	
Freiburg	8 0	Electric Supply at 6d.	60 0
Bellegarde	8 0 – 12 0	„ „ 3d.	30 0
Zurich	7 10 – 16 0	*Gas.*	
Heilbronn	42 0	Gas at 3s.	12 0
		„ 2s.	8 0
		„ 1s. 6d.	6 0

The figures, in some cases, will hardly bear separation from their explanatory context, but this has been given in our columns, and even a gas engineer will hardly compare the price of water power in the North-West of the United States with the maximum charge of the London Hydraulic Supply Company. To these figures may be added the annual cost of steam-power according to the independent, but remarkably coincident estimates of Mr. SWINBURNE and of Messrs. CROSS and BEVAN, namely £6.11s. per horse-power-year of 8,760 hours.

At the commencement of his third lecture Professor UNWIN called attention to the way in which the cost of steam-power and that of water-power was affected by the length of a working day. Until the full text of Prof. UNWIN's lectures is published, there is an ambiguity about the horse-power-year. In some cases it means 300 days of 10 working hours. A horse-power-year, if it means anything, means work done at the rate of one horse-power for 365×24 hours, and if we ask Niagara or the Rhone to signify their assent to modern ideas by adopting the eight hours system their only reply is a rise of 300 per cent. in the cost of the power which they provide.

OBITUARY.

HENRY-JOSEPH ARCHEREAU.

The death is announced of M. Henry-Joseph Archereau at the age of seventy-three. The deceased made a name for himself in the middle of the century by his work on the Bunsen cell, and by his arc lamp. Later on M. Archereau suggested the idea of converting coal-dust into briquettes, a form of fuel now largely used on French locomotives.

M. Archereau came to Paris in the last years of the reign of Louis-Philippe, and in 1849 made the sensible and obvious improvement to the Bunsen cell of placing the carbon inside and the zinc outside the porous pot, thus rendering the moulding of carbon cylinders unnecessary. He, at the same time, substituted retort carbon for the agglomerate carbon of Bunsen. In the Grove cell, as originally arranged in 1839, the zinc was inside the porous pot and the platinum foil, rolled into a cylinder, was outside. Science had very lofty notions in those days, so much so indeed that although Grove investigated the question of using cheap carbon instead of costly platinum as the negative element of his cell, he was of opinion that scientists would deem the use of carbon scarcely in harmony with pure science, and so said nothing about his work in this direction, with the result that carboned Grove cells were soon being sold as "Cooper" cells by a Charing Cross optician. However, the high price of platinum necessitated some kind of recognition of existing facts, and the first arrangement of the elements was soon reversed. Bunsen, however, re-inventing in 1843 the carboned Grove cell, adhered to the original arrangement of the elements, using carbon cylinders. About the time that M. Archereau came upon the scene many people were at work upon the task of getting rid of the noxious fumes given off by the nitric acid cell. Some tried hermetic sealing; others absorbents, such as oleic acid. M. Archereau attempted with but moderate success to overcome the defect by placing an inverted vessel containing iron-filings over the cell. Another device of M. Archereau was an elaborate contrivance for filling and emptying large electric lighting batteries of a hundred or more cells, which could, it was claimed, be filled in this way in five minutes. In 1850, M. Archereau brought out an arc lamp in which the lower carbon holder was actuated by an iron-copper core moving within a helix of wire traversed by the main current, the balance being maintained by a counter-weight.

Fortune did not smile on M. Archereau, but for many years he was maintained in comparative comfort by the liberality of the late M. Gaston Planté. A few years ago M. Archereau's friends got up a subscription on his behalf, but the small sum realised was wasted on profitless inventions, and M. Archereau finally died in misery.

REVIEWS.

Pioneers of Science. By OLIVER LODGE, F.R.S. (London: Macmillan and Co.)

Since the pioneers of science, whose lives and labours have been related by Dr. Lodge in a course of eighteen popular lectures, were, almost without exception, astronomical pioneers, some justification is, perhaps, necessary for reviewing the book, into which these lectures have been converted, in the columns of a journal devoted solely to electricity. Our excuse cannot, it is certain, be that references to electrical science and its bearings upon astronomy are to be found strewn up and down the volume in a sort of milky-way fashion. On the contrary, the only mention of electricity that we can call to mind is that on p. 343, where allusion is made to the hypothesis that a possible, if not probable, cause of the peculiar wag of comets' tails as these erratic bodies approach the sun is electric repulsion, due to the sun and the tail being similarly electrified. For us the chief attraction of Dr. Lodge's lectures lies in the very fact that they deal with a subject outside our own, with a science far more entitled than electricity to be called "Imperial." A branch of learning in which infinity is no longer a mere mathematical abstraction, but something like a solid fact, and eternity is made well-nigh comprehensible, which comes into contact, more or less close, at every turn with geology, chemistry, optics, climatology, and electricity, and is concerned with the past, present, and future, not only of the human race and the solar system, but of the universe, surely approximates more nearly to an Imperial Science than the comparatively limited dominion governed by the laws of electricity and magnetism.

From first to last the lectures are instinct with the vigorous style and somewhat combative spirit of the lecturer, although naturally more scope is found for the exercise of these powers in the earlier discourses dealing with the dawn of modern astronomy and the poverty and persecutions of the adherents of the cause of progress than in the later ones referring to more prosaic times. A persevering but hardly successful endeavour is made by the author to assume what is considered by polite society to be the correct attitude in these days in regard to the ancient battle between science and its persecutors, to wit, an attitude of "not blaming over much." One ingenious and, it must be confessed, wholesome device of the author is to balance every instance of theological obstinacy by a piece of "petrified professorial wisdom," such as that of the Padua pedant who refused to inspect Jupiter through Galileo's telescope for fear he should see the satellites and have to admit their existence. An Act of Oblivion is, however, no doubt on the whole the best thing, though it is right that all students of science should know what has rendered such an Act necessary.

By a strange irony of fate the founder of modern astronomy, with all the tremendous consequences it involves, was Copernicus, an obscure and wholly orthodox Polish monk. Within a few years of the death of Copernicus, Tycho Brahé was born, and although more famous amongst his contemporaries for his ingenious artificial nose than for his astronomical discoveries, the accuracy of his observations remains a marvel to this day. Then came Kepler, with his dire poverty and laborious gropings and discovery of the elliptical path of the planets and the laws governing the length of their year. The next name of note is the venerable one of Galileo, almost as memorable for his tragic battle with the powers of darkness as for his attractive personality and glorious services to science. Although it is impossible, even at this distance of time, to read the oft-told tale of Galileo and the Inquisition without a feeling strikingly like unto indignation, it cannot be gainsaid that Galileo courted his doom. Throughout his life he seems to have given way to the fascinating but highly-dangerous pursuit of making the powers-that-be look foolish, and his publication of his "Dialogues on the Ptolemaic and Copernican Systems" on his return from Rome was an imprudence which almost merited the terrible punishment meted out to it. We are certainly bound to tell the truth that is in us, but not necessarily at all times, and in an irritating manner. After Galileo we come to Bacon, that precursor of fashionable science of the Friday Evening Discourse order, to whom Dr. Lodge naturally does not allot quite so prominent a niche in the Temple of Science as the literary critic almost invariably does. After a chapter on Descartes and his theory of vortices, we come to three on Newton, whom the author regards as superhuman, though his superhumanity unfortunately did not save him from being elected a member of Parliament, nor from being involved in one or two of those miserable squabbles which so frequently disturb the calm of the scientific world. Bradley, the discoverer of the aberration of light; Laplace and Lagrange, who mathematically demonstrated the stability of the solar system (from insufficient data alas), and first propounded the nebular hypothesis; Herschel, the founder of stellar astronomy, occupy the next five chapters. The remainder of the volume is taken up with the discovery of Neptune, comets and meteors, the tides and planetary evolution, the closing lines being devoted to the dismal task of proving that the moon will one day crash back upon the earth, which, by the way, only escapes a daily destructive meteoric bombardment owing to the fact that it has a skin of air adhering to it, the friction of which is sufficient to reduce the meteoric bombs to vapour, moving towards the earth, as they generally do, with a total velocity of about 162,000 miles an hour. The inhabitants of a planet, the habitability of which hangs upon a thread so thin, may look forward to the contingency of its being crushed out of existence a few million years hence with "sombre acquiescence," if not cheerful resignation.

The Year-book of Science for 1892. Edited by Prof. T. G. BONNEY. (London: Cassell and Co.)

This volume consists of a digest of Papers read before certain scientific societies, and of articles contributed to scientific journals and periodicals. The first section, Physics, is divided into General Physics, Physical Astronomy, and Metereology. The sub-sections of general physics deal with the subjects of electricity and magnetism, and in 74 pages give a number of interesting abstracts. The index is by no means so complete as it should be in a book of reference of this kind. The names of authors or investigators are not given in it; a very serious omission.

Annuaire pour l'An 1893. Bureau des Longitudes. (Paris: Gauthier Villars et Fils.)

The Bureau des Longitudes was created by the National Convention, under the law of the 7th Messidor Year III. (June 21, 1795), and one of the duties of the Bureau was the annual publication of an almanack, which should serve as a model to the whole Republic. Last year a new era was inaugurated, the dry tables of the Annuaire being supplemented by scientific articles of current interest. In the present issue this new departure has been carried still further. M. Cornu contributes an article, of over 70 pages, on the correlation of electrostatic and electro-dynamic phenomena, and the definition of electrical units, while M. Janssen has something to say about the Mont Blanc observatory. The table of magnetic elements has been extended by M. Moureaux, and now includes every *chef-lieu d'arrondissement* in France. The Annuaire contains a mass of accurate and useful scientific data, and is, moreover, provided with an admirable index. The editing committee consists of MM. Janssen, Cornu, Lœwy, and Tisserand.

Laxton's Price Book for 1893. (London: Kelly and Co.)

This well-known handbook has reached its seventy-sixth edition, and has been further enlarged and improved. An index printed on the edges of the book, as in "*The Electrician* Electrical Trades' Directory," facilitates references to various trades. The prominence given to patented or proprietory articles in such a book is unavoidable, but as a result, a number of ordinary materials and fittings are omitted. Turning, for example, in the index, to "Gas burners," a matter on which we are supposed to be completely ignorant, but on which we are glad to receive information, we are referred to page 338, but find no reference whatever to the still-surviving productions of Bray, Peebles, and Sugg. Some historian in 1993, on consulting a copy of this book in the

Hosted by Google

British Museum, might hastily conclude that these useful inventions had already been swept away by the advent of electric lighting. The section on Electric Lighting must needs begin with a dissertation on absolute units, and definitions of which the following is an example: "Electromotive force (mostly written E.M.F.) is the name used to express the force which tends to move electricity from one place to another, and is proportional to the difference of potential of the two places." It is generally considered sufficient that the engineer in charge of electric lighting plant should have a special knowledge of the subject, but we note that "The Brush Electrical Company manufacture engines with a special knowledge of the requirements for electric lighting." The prices of electrical machinery, &c., appear to be fairly representative.

House Lighting by Electricity. By ANGELO FAHIE, Inst.C.E.I. (London: E. and F. N. Spon.)

The author of this latest addition to the host of shilling guides to those about to "go in for" electric lighting has succeeded in turning out a very fairly useful little *brochure*, useful, that is to say, from the consumer's point of view. We are not prepared to go bail for the absolute accuracy of every statement, definition, and analogy contained in the eighty pages which go to make up the book, but there is less science and more sense than is usual in such publications. The advantages of electric lighting are naturally made the most of, but there is no hocus pocus with the figures in getting out the relative cost of gas and electricity. The hints to users in the last chapter are really serviceable, and the appendix giving approximate cost of wiring and lighting various sized houses seems as reliable as any general estimate can be. The author has an ingenious theory by which he accounts for the statement so commonly heard that glow lamps are trying to the eyes. His idea is that people *will* stare so at glow lamps, and that when they cease to be novelties people will cease to stare at them, and complaints will die out.

Calvert's Mechanics' Almanack. By WM. CALVERT. (Manchester: John Heywood and John Calvert.)

This publication is now in its twentieth year, and, as its title denotes, its contents are intended for consumption by mechanics. Amongst other items of information we note an interesting article on "Patents," by Mr. W. Lloyd Wise, and a somewhat behind-the-time note on "Lightning Conductors." Dr. Oliver Lodge's Mann Lectures are now six years old, and the important practical fact brought out by them, namely, that for lightning rods iron is, at least, as good as copper from the electrical point of view, should surely have soaked down by this time into a note intended for practical workmen.

Index to the Journal of the Institution of Electrical Engineers. Vols. XI.-XX., 1882-91. Compiled under the direction of, and edited by, F. H. Webb, Secretary. (London: E. and F. N. Spon.)

As we recently announced, the suggestion thrown out by Prof. Ayrton in the opening sentence of his Presidential Address to the Electrical Engineers that the issue of a complete Index to the second ten volumes of the *Journal* would be an appropriate method of marking the arrival of the Institution at the end of the second decade of its existence, bore fruit, and on the last day of the old year the Index in question was in the hands of the members. We venture to think that the money which has been devoted to this work could not have been better spent, and that the members of the Institution and others will find this compilation both well done and exceedingly useful. Perhaps the most helpful feature of the combined Index is the printing of the titles of Papers actually read before the Institution in heavy type. The main Index occupies over 100 pages, and that relating to the Abstracts runs to nearly 80 pages.

Professional Papers of the Corps of Royal Engineers. Edited by Capt. W. A. GALE, R.E. Vol. XVIII. (Chatham: Royal Engineer's Institution. London: Simpson, Marshall and Co. 1892.)

This volume contains papers by Major R. H. Brown on "Egyptian Irrigation"; by Capt. S. D. Cleeve on "Application of Works to Irregular Ground"; by Mr. Graham Harris on "Electric Welding"; by Mr. Kapp on "Alternating Currents of Electricity"; and a very elaborate and fully-illustrated treatise by Mr. G. Bodmer on "Hydraulic Machinery."

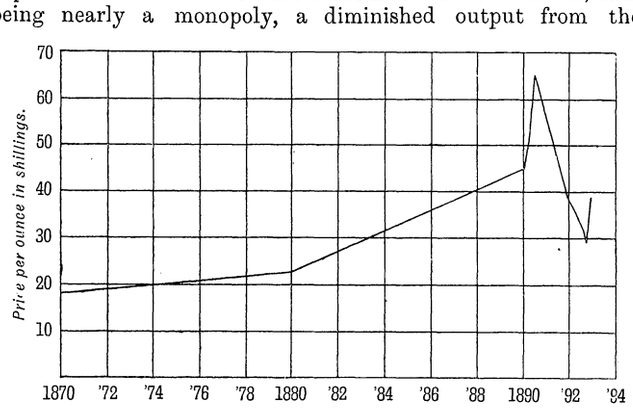
THE ST. LOUIS AND SUBURBAN RAILWAY.

In view of the forthcoming Convention of the National Electric Light Association at St. Louis, the *Electrical World* has commenced a well-written and well-illustrated series of descriptive articles on "The Electrical Side of St. Louis." The article in our New York contemporary's issue of February 11th relates mainly to the St. Louis and Suburban Railway, the most noteworthy feature of which is the fact that in October, 1891, it changed over at one step from steam and cable traction to electricity. The mileage of the line is 24½, and the car equipment consists of 74 motor cars and 62 "trailers," each of the former being provided with two 15 H.P. single-reduction T.H. motors. Owing to the high speed of 25 miles an hour which is attained outside the town, double bogies are almost entirely employed. The system of the Company consists of two lines, running from the heart of St. Louis into the suburbs, one of the branches stretching to a place called Florissant, 15 miles away. As "an incentive to travel" the St. Louis and Suburban Company purchased some 60 acres of land near the line, laid it out in orthodox pleasure-ground fashion, and dubbed it Ramona Park. The district through which the line runs, outside the town, is undulating and well wooded, and the advent of the electric cars has run up the value of land 100 per cent. and more in six months; as no doubt it was intended to do. Mindful of the likes and dislikes of the travelling public, the Company provides closed cars, even in the hottest weather, and alternates non-smoking with smoking cars, so that the devotees or opponents of the fragrant weed need only miss one car and wait three minutes before their speciality comes along. A letter and parcel post per electric car has also been inaugurated.

The power station is at De Hodiamont, six miles from the St. Louis terminus. The station has an area of over 14,000 square feet, and contains three 750 H.P. Hamilton-Corliss engines, ten 100 H.P. multipolar Thomson-Houston generators, and two 270 H.P. generators of the same type and make, all direct belt driven. The length of the longest feeder is 12 miles, and the pressure at its station end is 540 volts. The worst gradient is one of 3½ per cent., and it is one mile in length.

THE PRICE OF PLATINUM.

The supply of platinum is in the hands of so few dealers that the real history of the recent rise in the price of this metal is difficult to discover. Until recently the supply of raw ore depended on contracts held from the Russian Government, and, being nearly a monopoly, a diminished output from the



Curve showing Fluctuations in the Price of Platinum from 1870 to the Present Time. These Prices do not include the Cost of Manufacture into Plate or Wire.

mines, together with the rapidly increasing demand for platinum wire in lamp making, as well as the steady consumption for chemical and dental purposes, sent up the price rapidly from 22s. 6d. in 1880, to 45s. in 1890 reaching no less than 65s. in June of that year. It seems probable that this price was quite artificial, and it must have fallen rapidly, even if new sources had not been opened. But the sudden collapse

Hosted by Google

in 1891 came as a surprise to those who had accumulated no small stock of platinum, under the impression, no doubt, that the natural supplies were nearly exhausted, or were, at all events, quite unable to meet the demand. The decline has, however, been due to a large extent to the development of mines in British Columbia and although there has been a slight advance lately, the present prices will probably be maintained. The prices given in the diagram are for raw material, and do not include the somewhat expensive process of manufacture. We are indebted to Messrs. W. and J. Jamieson, of Broad-street, Golden-square, W., for assistance in compiling these particulars. In a letter to *The Chamber of Commerce Journal*, Messrs. Matheson and Grant say that they have before them a sample of platinum from mines in British Columbia which are in full operation, and from which a considerable quantity has been sold in London during the last two years, as much as 1,000 to 1,500 ozs. having been annually produced since 1886, all from placer mining. From the present hydraulic mining the production can be considerably increased.

DOULTON'S VITRIFIED STONEWARE CASING FOR ELECTRIC MAINS.

Messrs. Doulton and Co. are offering a stoneware casing for underground mains, made of their well-known, highly vitrified stoneware. It possesses great strength, and therefore affords a very perfect mechanical protection to insulated cables. The makers state in a circular that the casing is made in lengths of three feet or less, with two or more separate ducts. The interior surface has a hard and smooth glaze, presenting exceptional facilities for drawing cables in and out of the "ways."

Where it is necessary to maintain the complete separation of the ducts where the lengths are connected, the joint shown in Fig. 2, as applied to a 2-way casing, may be adopted. The method is as follows:—The lengths of casing are laid in the collars with a small space between them. Mandrels with indiarubber heads are then introduced into the ducts, and when opposite the joint between the lengths are expanded by a screw. Cement is then poured in, and this fills up the space between the casings except where occupied

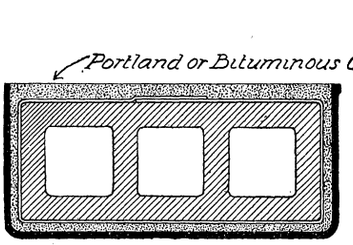


FIG. 1.—Cross Section of 3-Way Casing at Joint.

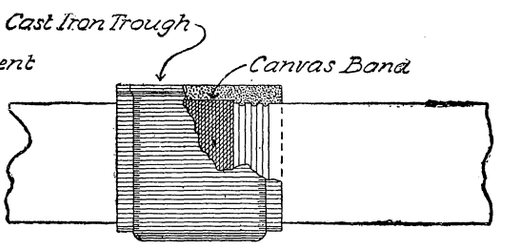

FIG. 1A.—Detail of Joint.

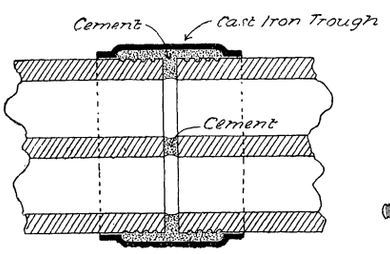
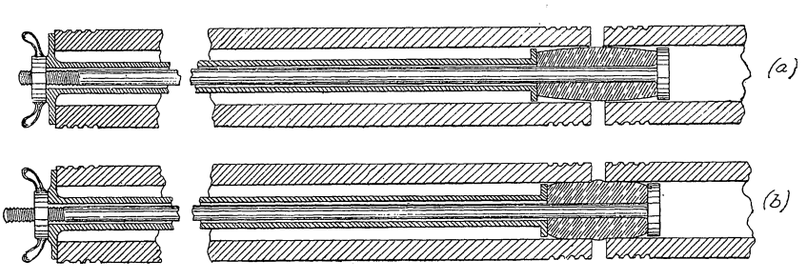
Several methods of joining the lengths of casing have been designed. A simple and efficient joint is shown in Fig. 1. The ends of the casing when brought together are lapped round with a band of prepared canvas, and enclosed in a stoneware trough open at the top. The lower interior surface of the trough, before being placed in position, receives a layer of Portland cement, which is prevented from entering between the casings by the canvas band. by the mandrels. In two to three minutes the cement will be set, and the mandrels are unscrewed and withdrawn. Small changes of direction at the joints can be made with the above-described modes of connection. In systems of distribution in which any considerable change of direction is effected by the introduction of a draw-box into the line, Messrs. Doulton are prepared, if required, to provide specially made water-tight stoneware boxes with iron



Horizontal Section of 2-Way Casing at Joint.



Detail of Expanding Mandrel. (*a*) As introduced into Duct. (*b*) Expanded to close Duct.

FIG. 2.

The trough is then filled to its upper edge with cement. Where space is a consideration, a light cast-iron collar or trough may be substituted for the stoneware, as shown in Fig. 1A, the same method as last described being adopted; or the trough may be simply filled with bituminous or other cement, the canvas band being used as above described.

surface-frames and covers to suit any requirements, where the opening does not exceed 2ft. 6in. in its greatest dimensions. The jointing of stoneware tubes by ordinary methods is always attended with some difficulty, and the strength and simplicity of these casings should command the attention of electrical engineers and contractors.

THE DEVELOPMENT AND TRANSMISSION OF POWER FROM CENTRAL STATIONS.*

BY PROF. W. CAWTHORNE UNWIN, F.R.S.

In opening his last lecture the lecturer said he found he had a little exaggerated the cost of hydraulic power in London. He gave as the lowest price 2s. per thousand gallons; he found that to large consumers it was supplied at 1s. 6d. per thousand. That gave a cost of £35 per effective horse-power per annum.

Distribution of Power by Steam.

Most commonly, where steam power was used, the boilers which generated the steam were close at hand. But in special cases it had been necessary to convey the steam some distance before it was used in the motors. Sometimes pumping machinery underground had been worked from steam boilers above ground. It would, nevertheless, hardly have been thought very reasonable to of collecting and conveying the natural gas great distances it completely took the place of coal both in manufactories and for domestic heating. The cost of coal at Pittsburg was 4s. or 5s. a ton, and slack coal sold at from 2s. to 2s. 6d. a ton. In spite of that coal went absolutely out of use. They obtained gas there in enormous quantities from wells, and the first transmission was to Mr. Carnegie's works, a distance of nine miles. It was a new

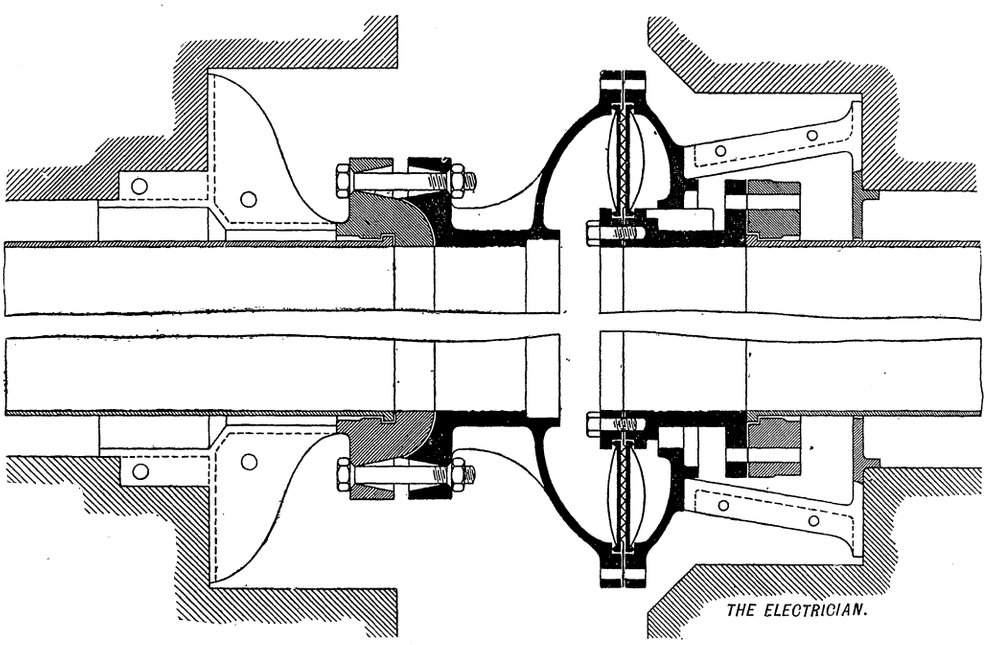
* Sixth and last Howard Lecture, delivered before the Society of Arts, Friday, February 17th.

Hosted by Google

distribute steam widely for power purposes through pipes, but the defects of steam as a means of distributing power might be balanced by its convenience as a means of distributing heat. At any rate, in America the experiment of distributing heat and power from a central station by steam had been tried on a very large scale and with a considerable amount of success. The first system was one started by Mr. Holley in a number of towns in America. There the steam was conveyed through pipes to the buildings to be warmed, and afterwards discharged through steam-traps into the sewers. Generally, before it was discharged it was taken through coolers over which the air entering the building passed, so that the steam was reduced before discharge to as low a temperature as possible. In New York, Mr. Emery concluded that steam could be distributed economically from one station to buildings within a radius of half a mile. In the first station were placed boilers working to 12,000 or 16,000 H.P. It might be judged that the system was not entirely unsuccessful from the fact that they were building up-town another station in which they had already provided for 3,000 H.P. They worked the steam at 80lb. or 90lb. pressure per square inch. The main pipes were of wrought iron, 15in., 13in. and 11in. in diameter, and the return mains were 8in., 6in. and 4in. in diameter, the idea being, of course, to bring back the hot water, and so save some of the heat which had been expended in the generating station. For steam used for heating, the charge was made on an estimate of the size and character of the building, and the amount of heat probably required. This method proved not very equitable or satisfactory. The charge for power was, for a time, based on the nominal power of the engine, and that also proved unsatisfactory. They appeared now to have contrived a steam meter which worked satisfactorily. It gave a graphic record of the amount of steam used. The ruling price at first was 50 cents per 1,000 "cals.;" * that was about ¾d. per horse-power hour. They now charged for either power or heating on a sliding scale, 70—40 cents. per 1,000 cals. That meant that they sold their steam power practically at from £12. 10s. to £7. 10s. per indicated horse-power per year of 3,000 hours. In the case of certain newspapers working chiefly at night the charge was reduced to £5. 12s. As these prices had been fixed after eight years experience it must be assumed that they left a possible margin of profit to the company. The pipes were laid in bricked trenches, covered with slag wool and roofed with boarding. There was an expansion joint at every 50ft. The expansion joint had been one of the principal difficulties of the system. A stuffing-box required too much attention and caused too much leakage. The ordinary diaphragm form of expansion joint did not give expansion enough for a 50ft. length of pipe, and the difficulty had at last been got over by an exceedingly ingenious expansion joint (*see* Figure) which Mr. Emery called the "variator." He used a thin corrugated copper diaphragm only 4-100ths of an inch thick. This was supported by a number of plates or girders on each side, which had more or less power of movement, and merely supported the expansion plate which made the joint tight. They had had a great deal of difficulty in New York of a practical kind. The loss of pressure in the mains over the area through which they supplied was not at all serious. But they had two other losses, the loss from radiation and the loss from leakage. They believed they had reduced those sources of loss to a comparatively manageable amount now. The radiation loss they though they could keep within 5 per cent. of the carrying capacity of the pipes. Of course the radiation in that case was serious, because they kept their pipes hot throughout the 24 hours. With a 6in. main with 45lb. steam pressure they could distribute through one main 260 H.P., and at 75lb. pressure 400 H.P. With an 18in. main, which was quite a manageable size, they could distribute through one main 2,400 H.P. at 45lb. pressure, and 3,500 H.P. at 75lb. pressure. So that they were not landed in any practical difficulty in regard to the size of main which was to be used in distributing any considerable amount of power.

Distribution of Power by Gas.

In the distribution of power by gas they had a problem in which there was nothing which was new or untried. Gas was manufactured on an enormous scale and distributed over town districts. It was enough to mention that in the United Kingdom there had been expended in capital account on gas undertakings £60,000,000; the amount of coal carbonised annually was 11,000,000 tons, and the amount of gas produced annually was 98 thousand millions cubic feet. At the cost at which gas was commonly sold, 2s. or 3s. per thousand, and taking the consumption of a gas engine at a moderately varying load as 26½ cubic feet per effective horse-power per hour, the result obtained in the Dessau station, then they found the cost of getting motive power by gas came out at from £8 to £12 per effective horse-power per annum. The cost included a very large amount due to the vast system of distributing mains which a gas company was obliged to have because it had to supply an enormous number of comparatively small consumers. They lost both in the interest on their mains and in the leakage from the mains. If they wanted motive power only in a manufacturing district a good deal of that could be saved. Even with ordinary lighting gas, it could then be supplied at a much lower cost than could be charged for ordinary lighting purposes. The actual cost of the manufacture of gas was 10d. per thousand cubic feet, and if they allowed 1s. 6d. to cover the cost of distribution over a manufacturing district with comparatively simple mains for motive power purposes, then the cost of power would work out at £6 per effective horse-power per annum. At Dessau the gas company had started an electric lighting station worked with gas engines, and it worked with considerable success. They gained by it because they could produce the surplus gas wanted at a cheap rate, and they gained because they retained the customers who elected to take the electric light. At that station they worked at about 160 E.H.P. In connection with gas he would just casually refer to the distribution of natural gas at Pittsburg, because there was a case in which gas, entirely for heating and motive power purposes, was enormously widely distributed. In spite of the cost



Emery Steam Pipe Expansion Joint.

* 30 cals. = 1 H.P. hour.

Hosted by Google

undertaking, and they arranged with Mr. Carnegie that they would put in the pipes and convey the gas to his works if he would pay for it the price he was paying for the coal it replaced up to the time the cost of the mains was covered. Then they would supply the gas to him at half the price he had previously been paying for coal. In that particular case the cost of laying mains was recouped in 18 months. The gas was then taken into Pittsburg, 18 miles away, and afterwards carried a distance of 100 miles. In connection with the distribution of gas for motive power, he found that at the ordinary pressure of 2½in. of water column a 6in. main would carry 250 H.P., and a 36in. main would carry 22,000 H.P.; so that there again they were not brought to any narrow limit in the amount they could distribute by the cost of the distributing arrangements. If they choose to adopt gas somewhat compressed they could distribute much more.

Transmission and Distribution of Power by Electricity.

Coming now to the electrical transmission of power, in 1877 Dr. William Siemens indicated the importance of electrical methods in transmitting power to considerable distances. In his address before the Iron and Steel Institute he stated that a copper rod, 3in. in diameter, would transmit 1,000 horse-power a distance of 30 miles. At that time he was not able to quote actual and practical working transmissions of power. There was very little else than the Lichtefelde and Portrush Railways. From the dawn of the science of electrical engineering the hope had constantly been put forward that now at last some advances had been made which would revolutionise the transmission of power. The world had been promised all things, even the working of railways and Atlantic greyhounds by electrical energy. He was ready to admit that electricians could do much, all, in fact, that they promised; with one proviso—that they were allowed unrestricted expenditure. The world, however, was not carried on on the principle of making unremunerative investments. In a great deal that was said about electrical distribution two things were forgotten; there had always been some means of transmitting power; that if electrical transmission was to become important it must be because it could be carried out so cheaply that the power could be delivered cheaper than power delivered in any other way. There were, indeed, certain directions in which electrical engineers had already achieved a great deal. In the field of electric lighting, which in one sense was distribution of energy from a central station, a great deal had been accomplished. Electric lighting appeared to be succeeding, although it was too early yet to estimate the measure of its sucess. In towns like Geneva, where gas was sold at 7s. per 1,000ft., electricity had not, even on the ground of cost, a formidable competitor. In other cases the unquestionable convenience of electric lighting balanced its extra cost. In the United States there were some four or five thousand miles of electric tramways working with perfect mechanical success. He could not discover that the cost of electric traction was, except in very favourable cases, much lower than the cost of horse traction, but electric tramways, especially in American towns, possessed great advantages over horse traction, especially in the matter of speed; within half a mile of the centre of Buffalo they ran their cars at 15 miles an hour. Almost without exception the electric tramways which had been successful had cheap overhead conductors carried on posts. With the more expensive systems suitable to towns in this country the financial success would be more problematical. A third case in which electricity was likely to achieve success was in the working of underground and overhead railways. Where a three or four minutes' service of passenger trains was required, electric motors distributed over numerous carriage axles had great advantages. It was possible that even in working cost the electric motor would be better than the steam locomotive. Putting aside the cases of lighting and traction, and looking to the transmission and distribution of power, the progress of electrical methods was very far less rapid. Mr. Shoolbred had mentioned in that room a case where, in Bradford, a demand arose for motive power from the mains for electric lighting, but the cost of the horse-power per annum was at 6d. per B.T.U. £60, a charge which made a large use of the power impossible except in cases of working intermittent machinery. Even if they supposed electricity sold, as it was sold in some cases, at 3d. per unit for motive power purposes only, the cost of the power would be £30 per horse-power per annum. There was an interesting case of the development of power at a considerable distance at Oyonnaz, near Geneva. There were turbines of 250 H.P. at Charmines which generated current at 1,800 volts, which was transmitted about eight kilometres to the village, where it was reduced in pressure and used partly for lighting and partly for driving workshops. Nothing could exceed the appearance of general prosperity of the place when he was there 18 months ago, but at that time only 30 H.P. for motive power and 40 H.P. for lighting was used. The Schaffhausen system was fully described by Mr. Kapp before that society. That station a year ago was only distributing power to a single factory. It was delivering electricity to work one 380 H.P. motor and two 60 H.P. motors. Just about the same time there was a similar installation worked by Mr. Hillaret, at Domêne, near Grenoble. There a turbine was erected in a gorge, and worked at 300 H.P. The gorge was almost inaccessible in winter time for about three months. A paper mill at a distance of five kilometres was worked in this way; the efficiency of the whole arrangement being 65 per cent. All those installations had three points in common: the electric current was continuous, the current was conveyed by bare wires on wooden posts, and the source of motive power was a fall of water. In the future, alternating currents might replace continuous currents. So far as he knew, it was only where water power was available and cheap overhead conductors could be used that electricity had been supplied at a distance at a price low enough to compete with other means of obtaining power.

A very important continuous current plant had been constructed at Genoa by MM. Cuenod-Sautter, of Geneva. At Genoa the possibility of an electrical supply had arisen in an exceptional way. Some ten or twelve years ago a scheme of water supply additional to that which already existed was matured, and works had been carried out, the level of the source being 2,050ft. above Genoa. The first service reservoir was at the end of a tunnel, by which the water was carried through a mountain ridge, and was 600ft. below the source. There 730 gross horse-power was available. The next reservoir was 360ft. below the first, and there again 730 H.P. was available. The third was 500ft. below the second, and there 1,000 H.P. was available. The water supply system was not altogether satisfactory. The water had a colour, and although it was perfectly healthy people disliked it. The engineer and consulting engineer were thus led to consider the utilisation of the fall in the mains for generating electricity for lighting and power purposes. At the three points indicated were three stations, the Galvani, the Volta, and the Paccinotti. The Galvani and Volta stations were in operation and the third was in the course of construction. The first installation of 140 H.P. was made in 1889 at the Galvani station. This proved successful, and the complete work was then undertaken. The Volta station supplied 15 motors distributed along the valley and actuated besides a motor of 60 H.P. in the railway station at Genoa. It also drove the dynamos of the central electric lighting station in Genoa. The rest of the power in this station, amounting to 600 H.P. at least, worked a telodynamic transmission. The Galvnai station supplied electricity for lighting the station of Sempierdarena, and drove a motor of 60 H.P. It also supplied power to a number of mills and factories and repairing shops connected with the railway. The transmission was a series constant current one. At certain hours all the motors were out of action; then the dynamos had to furnish only some 450 or 500 volts. At certain hours the dynamos for lighting the town were in action, as well as the other motors; then the voltage reached 5,000 to 6,000. The changes of voltage were sometimes extremely sudden. At the Galvani station, which was the first in which they made the experiment, they had a single group of machines consisting of a two Thury continuous current 6-pole dynamos coupled to a Rieter 140 H.P. turbine, having a normal speed of 250 revolutions per minute. In that case the regulation was effected by hand. The speed varied from 20 to 475 revolutions, according to the demand for power. The dynamos were coupled in series. The variation of speed there was effected entirely by varying the speed of the main turbine. Having succeeded so far with the first installation of 140 H.P. at the Galvani station, they proceeded to design the Volta station, and endeavoured there to carry out a more refined method of regulating the voltage. The Volta station was put in operation in 1891, and had been in successful working ever since. It consisted of four turbines of 140 H.P. each and eight dynamos working at 47 amperes and 1,000 volts at full load. These generators worked at constant speed, and the regulation was effected by varying the exciting current. The whole of the exciting current for the whole eight dynamos was governed by a single governor. The regulation of the current presented difficulties because the motors varied from moment to moment quite suddenly, as the motors driven by the current could be put out of action almost instantly by short-circuiting. To meet these conditions the exciting dynamo was driven by a separate 15 H.P. turbine, which had as little inertia as possible. The exciting dynamo had a very light armature, so that it followed instantly the variations in speed of the turbine driving it. The exciting dynamo was itself excited by a small machine lighting the station, and the stability of its magnetic field was thus secured. The turbine driving the exciter was provided with an ordinary relay governor, but the conical pendulum ordinarily used to secure the constant speed of the turbine was replaced by a solenoid holding in eqilibrium a soft iron core. This was directly attached to the valve of the relay. This system had given good results, but notwithstanding at the new Paccinotti station it was in contemplation to return to the system adopted in the Galvani station. For the transmission of the current there were bare copper wires ⅜in. in diameter, carried overhead on poles. The transmitting line had a length altogether of thirty miles, and a resistance altogether of 500 ohms, and the efficiency at full load was about 90 per cent. The motors were all

Hosted by Google

Thury motors, of from 5 to 60 H.P. From 5 to 18 H.P. they were bi-polar, and their regulation was effected by shunting. The motors of more than 18 H.P. were multipolar, and the mode of regulation was to reduce the power by making some of the convolutions of the field magnets receive current in the reverse direction. In that installation they reckoned that the ratio of the effective work on the motors to the effective work at the turbines was 72 per cent. That was a good efficiency, but it was not more than it was possible to obtain under conditions not very different by some other modes of transmission.

Another rather interesting transmission was at Biberist, near Soleure, also constructed by MM. Cuenod-Sautter. There they had turbines of 360 H.P., and power was transmitted 28 kilometres to a paper-mill. The generating stations had two Thury continuous-current dynamos coupled directly through Raffard couplings to the turbine, running at 275 revolutions. The current was transmitted at over 3,000 volts pressure by a bare copper overhead wire a quarter of an inch in diameter. An efficiency of 70 per cent. was guaranteed. The Lauffen-Heilbron transmission on the alternating three-phase system might next be mentioned The owners of some cement works having surplus water power conceived the idea in 1889 of utilising it by means of electricity for lighting and power purposes in the town of Heilbronn, six miles distant. They accepted plans for a a three-phase current plant. The current was produced at Lauffen at 5,000 volts pressure, and at Heilbronn it was first reduced to 1,500 volts, and then to 100 volts. The cost of the current for lighting purposes was 9d. per kilowatt hour, and for power purposes 4d. per kilowatt hour; that worked out at about £42 per horse-power per annum, without allowing for the interest on the cost of the motors. In November last there were eleven motors in Heilbronn, aggregating altogether 32 H.P., so that it was quite an insignificant affair. It was too early to say whether, even at the prices charged, this transmission and distribution could be regarded as commercially successful. So far as he had any means of judging, the three-phase method proved to be an expensive method of working. Mr. Brown, who designed the Lauffen dynamo, never spoke very strongly in favour of the transmission. He had said that one object of the Lauffen-Frankfort installation was to show the advantages of the three-phase system, but it actually showed the disadvantages of complication in the line, generators, and transformers.

Looking to accomplished results, it appeared that electricity generated by steam was nowhere supplied at less than from £30 to £40 per horse-power per annum, exclusive of the cost of motors. Its use at that price was necessarily limited. On the other hand, there were important cases of distribution which had been described, besides some in America, where it been successfully carried out, where power was initially obtained from water, the cost of power being nothing more than the interest on machinery for using water power. There was no prospect of a reduction in the cost of electrical distribution. In one case it seemed to a non-electrical engineer that the cost would have to be increased, for wires on telegraph posts did not suggest adequate security or permanency in a great power distribution working, as such a distribution must work, night and day all the year round, and on which the industrial life of a whole community would depend. The smallest self-respecting town in requiring a water supply would not hesitate to build a substantial conduit. An important power distribution did not seem to require less permanent construction than a water supply, and such a conduit would carry conductors free from risk from lightning and much freer from risk from accident than telegraph poles. But, of course, if a conduit of that kind had to be adopted the cost of distribution would be increased.

Referring to the Herstal plant in Belgium, the lecturer said it had been always a question where steam power was used of how far it was desirable to centralise the power or to distribute it. There had been cases where each principal shaft was driven by separate motors. In some large works at the present time they were replacing steam engines by scattered gas engines. It was found at Birmingham that one of the advantages of compressed air power distribution was that a considerable amount of shafting could be dispensed with in some of the workshops, and separate air motors could be distributed over the works; the motors required very little attendance, and they did not, like small steam engines, fall off in efficiency because they were small.

The Future of Power Distribution.

It had been shown that where power was easily and cheaply obtainable the demand for it grew, and the advantage to the community was very great indeed. Power could be distributed in various ways at a cost varying partly with the original cost of power, and partly with the interest on the distributing arrangements. There was no hope that the cost of the distributing arrangements could ever be made small. The engineer therefore was forced to study modes of cheapening the sources of power. Where water power was available it had enormous advantages, so great that its utilisation would probably lead to a transfer of industries in many cases to new localities. As to steam engines, probably the limit of improvements had very nearly been reached. With gas engines there was perhaps a larger, through not very large, prospect of reducing the cost at which power could be produced. In central station working by steam, the cost of working was the chief difficulty. The fundamental difficulty was the variation in the demand for power and the expensiveness of any means of storage of power hitherto tried. The variation of the demand had led the London gas companies to discover the advantage of combining with their primary object of lighting, the supply of power and the supply of heat. In his address to the Gas Institute two years ago Mr. Trewby said there were 2,500 gas engines and 70,000 gas heating stoves in London. Comparing two similar days in June, 1880, and June, 1890, it could be seen that the night consumption chiefly for lighting between 8 p.m. and 3 a.m. had increased 20 per cent. in ten years; in the same ten years the day consumption of gas in London had increased 73 per cent. That was chiefly due to the increased employment of gas-engines and stoves. In Paris compressed air was used for driving refrigerating machinery, for driving an electric light sub-station dynamos, and for ventilation. At Cologne the water supply and electric lighting stations combined, so that when power was not required for lighting it was used for pumping. At Dessau the gas company erected an electric lighting station on the principle that the use of gas in driving gas engines increased their profits as gas engineers as well as obtaining for them new customers. *The chief hope of reducing the cost of power distribution would be by combining the supply of as many demands as possible.*

LEGAL INTELLIGENCE.

Tibbits v. Alabaster and Others.

This case, part of which was briefly reported in our last issue, was opened on Wednesday, the 15th inst., before Mr. Justice Mathew and a special jury. The action was brought by Herbert Tibbits, M.D., against the proprietors of the *Electrical Review*, in respect of an alleged libel published in that paper. The defence was that what was published was fair criticism on a matter of public interest, and, therefore, justified.

Sir R. Webster, Q.C., M.P., Mr. R. Wallace, and Mr. R. A. Germaine were counsel for the plaintiff; Mr. Lawson Walton, Q.C., and Mr. Bankes appeared on the other side.

Sir RICHARD WEBSTER, in opening the case, said that the action was brought by Dr. Tibbitts in respect of a libel, in the sense that it imputed misconduct as well as ignorance to Dr. Tibbits. Dr. Tibbits was a medical man, an M.D. of the University of Edinburgh, and possessing, in addition, considerable qualifications in England; and he had for a long time been interested in what was called "massage and electrical" treatment of complaints. The defendants were the proprietors of an electrical paper who had thought fit to make a series of attacks upon the treatment that would be the subject of discussion in this action, and to include therein anybody who had expressed an opinion, however honest his opinion might be, and however well-grounded, having regard to his own investigation. There had been established at 52, Oxford-street, for some years an institution on which a very large amount of money—between £40,000 and £50,000—had been spent in fitting it up with the most elaborate and improved appliances for electrical treatment. Quite apart from the electrical treatment that went on in the institution itself, Mr. Harness had invented what was called Harness's Electropathic Belt. Dr. Tibbets was asked by Mr. Harness to examine his methods and make a report. Dr. Tibbits said he would do so, but his report must be taken whether it was good or bad. Mr. Harness agreed, and undertook to pay the plaintiff a fee of 100 guineas. The learned counsel then referred to what he termed the libel written concerning the plaintiff, and published in the *Electrical Review* of September 23, 1892. It was headed 'Electricity and the Medical Profession," and referred to the pamphlet on the "Treatment of Disease by the Prolonged Application of Currents of Electricity of Low Power," by Dr. H. Tibbits, as a grave reflection upon the intelligence of the medical profession generally, seeing that Dr. Tibbits was supposed to be a recognised authority in the medical world. It proceeded: "A perusal of the foregoing by any one who has a very elementary knowledge of galvanic electricity, and who has one of the Harness belts before him, will at once show that the writer exhibits a most incredible ignorance of electrical laws, an ignorance which utterly unfits him to speak as an authority, and which in view of the support which it affords for the bolstering up of this appliance, seems to call for an interdiction by the British Medical Association. . . To get at the public, so as to protect them, is most difficult; the daily Press is, unfortunately, too interested, from an advertisement point of view, to enter into the matter. Although it may take time, we feel little doubt but that perseverance will eventually command it, and that what is undoubtedly a grave scandal, may at last be unveiled in all its grossness, and the promoters and abettors brought to book." He (Sir Richard) might tell them "interdiction" meant the preventing of a man being allowed to carry on his medical practice. If the Medical Council chose, they could remove a man from their rolls, and prevent him carrying on his profession. He called attention to the fact that Dr. Tibbits was charged with almost incredible ignorance of electrical laws—ignorance which it was suggested had been so applied as to render his "interdiction" desirable. It did not follow because continuous currents were sneered at from a scientific point of view, that they were useless; in fact, there was an overwhelming amount of

Hosted by Google

testimony that the benefit derived from these belts had been immense. That what had been read was a libel there could be no doubt. To charge a professional man with imposture, and to say that he was an abettor of a gross fraud, was calculated to do as much harm to a medical man as could well be imagined. It was particularly hard on Dr. Tibbits, because he was a bankrupt. His bankruptcy, however, had been caused by an enthusiastic (it might be a rash) desire to promote a hospital for the poorer classes, where the processes he had started and developed for the treatment of diseases should be carried out. In conclusion, the learned counsel submitted that in the face of what he should prove Dr. Tibbits knew when he wrote the report in question, to speak of him in the way this libel had done was a gross and slanderous libel, entitling Dr. Tibbits to very substantial damages.

The plaintiff was then called, and bore out his counsel's opening statement.

Cross-examined by Mr. WALTON: Dr. TIBBITS said he was bringing this action for his own benefit exclusively. Mr. Harness was finding the money to carry it on. He explained his connection with the West-End Hospital and the West-End School of Massage. He disapproved of both the *Lancet* and the *British Medic l Journal*. Mr. Harness simply gave him the belt. He had not seen any belt without external connections, but his opinion at present was that they should all have them.

In reply to further questions, Dr. TIBBITS adhered to his opinion that some current did pass through the body.

Would the experiment I have referred to lead you to say that either quantity or intensity could be obtained?—The intensity refers to the belt when not worn. It was not written to be cross-examined on by a learned counsel in a law case. (Laughter.)

Mr. JUSTICE MATHEW: We are not here to try the belt.

Re-examined by Mr. WALLACE, the plaintiff said his first experiments were with the belt detached from the body. Then he proceeded to see whether the current, instead of going outside, went inside the body. All the moneys he received from the bazaars went to the hospital. He made himself responsible, and the last resulted in a loss of £1,500, which sent him into the Bankruptcy Court. The School of Massage was carried on first at the hospital, and afterwards at a house close by.

Dr. ARTHUR JOHN HARRIES and Dr. RUSSELL HARRIS were called, and gave it as their opinion that the belts which had been submitted to them generated a current of electricity which, when applied to the body, passed through.

Mr. J. W. WILSON, C.E., said he was the principal of the Engineering School at the Crystal Palace. He was one of the jurors in the Electrical Exhibition of 1892. The belt produced, when coupled up, generated electricity. He had no doubt it would, when placed upon the body, pass through it.

Cross-examined by Mr. BANKES: He wrote to Mr. Harness and asked him to send a belt, as he (witness) thought he would like to see what it was. He wore it some time, and then tested it. Subsequently Mr. Harness obtained a report from him. There could not have been any stream of electricity in the manner suggested in his first testimonial. He supposed he had made a mistake. Mr. Harness asked him to examine seven belts, and he paid him fifty guineas.

Mr. H. F. JOEL, an electrician of over 25 years' experience, said he had had about ten of the belts submitted to him He found that each and every one did generate electricity. He had tested the electromotive force, the resistance and the quantity of electricity. Beyond all doubt, the greater part of the current must go through the body, as the part that offered the least resistance.

Cross-examined by Mr. BANKES: Mr. Joel said he was an electrician pure and simple. Any pieces of copper and zinc coupled up and placed in anything that would act as an electrolyte would produce electricity. Four of the discs neutralised each other and the other two gave a resultant current. The most he obtained was $\frac{2}{10}$ths of a milliampere.

Mr. S. J. MACKIE, C.E., of 27, Chancery-lane, for 27 years the science correspondent of the *Standard* and other journals, said he had come to the conclusion the belts generated electricity which went through the body. When the belt was on the body he obtained a click from the telephone.

Cross-examined by Mr. BANKES: When coupled up the belt gave 1·4 micro-amperes.

THURSDAY, FEBRUARY 16TH.

Mr. LAWSON WALTON, Q.C., in opening the case for the defendants, said that the defendants who invited the jury to express the opinion that they had exercised fairly their right of criticism, and expressed frankly their opinion and their censure of an appliance sold to the public, and which the public were invited to purchase, were men who could form an opinion of some weight, and who claimed to have formed in this case a perfectly honest, a perfectly dispassionate opinion, and one which he trusted they would hold, fell within the domain of fair criticism. This action was important to the defendants; it was none the less important to the public. The right to think and form an opinion upon, and, if necessary, to condemn, any one of the various new appliances of science which were seeking a public market, and were apt to impose upon the uninstructed and credulous members of society, was a right which ought not to be lightly invaded The whole attack had been on the appliances—a censure on those who sold the appliances, and on those who made large profits by putting upon the market what these gentlemen (the defendants) honestly thought—and thought for good reasons—to be an utterly worthless article of trade. In his opinion, before Dr. Tibbits lent his name to Mr. Harness in connection with the publication recommending the public to purc ase the belt, he ought to have said he confined himself to the mere abstract scientific inquiry whether electricity could be generated by the belt or not. He maintained that the article did not attack the plaintiff, but denounced in the strongest terms the action of Mr. Harness, who must have smarted from head to foot when he read the opinions of the writer. Mr. Harness, however, had not brought the present action.

Sir RICHARD WEBSTER, interposing, said there was an action by Mr. Harness pending.

Mr. LAWSON WALTON, continuing, said Mr. Harness had brought no action with reference to the article in question, but had commenced another action, which the defendants would deal with when it came on for trial. At all events, looking at the position of Dr. Tibbits, it was manifest that this was really an action by Mr. Harness, and that he had found the means for it. There could be no doubt that Mr. Harness was the real plaintiff in this action and "financed it," and yet he had not been called as a witness. The action was really brought by him to punish the defendants for free criticism on his belts. The pamphlet put forth by him had actually been sent to their paper for the purpose of review, and they had the right to criticise it and the appliance it was sought to puff. It would be proved that the belts were sold and worn in the ordinary course, without the outside connection, which was with a view of attaching the appliance to a battery. The wire was sold loose, for attachment or detachment. Not a single member of Mr. Harness's staff had been called to show that the defendants were under a misconception with regard to that. The jury would be asked to come to the conclusion that Dr. Tibbits had ignorantly or negligently attached his name to an opinion which would encourage the sale of the belts. Lord Kelvin's, otherwise known as Thomson's, galvanometer, an instrument of remarkable delicacy, had been used in such a way as not to test the current passing from zinc to copper, but from zinc to the platinum pin inserted. Of course, what should have been done to prevent the independent current being set up, would have been to insert two platinum pins.

Lord KELVIN, the President of the Royal Society of London, said he had made a life-long study of electricity. One of Mr. Harness's electropathic belts had been submitted to him for examination.

Sir RICHARD WEBSTER submitted that the belt must be shown to be similar to that given to Dr. Tibbits.

Mr. W. T. A. BEARE, of Finchley, was interposed to depose to going to the Zander Institute in 1892 and purchasing a belt for 5 guineas. The belt was the one produced He took it to the offices of the *Electrical Review*. He asked how the electricity was generated. He never asked what the sockets on the belts were for, but he saw the sockets. He had not seen the internal arrangements of the belts, and knew nothing about them. There were no external wires on the belt. Re-examined: Absolutely nothing was said to him about outside connections on the belt—there were none. His attention was not called to any directions.

Lord KELVIN said that the belt if worn on the body in its present condition was not capable of generating any electricity on the body. He had seen a copy of Dr. Tibbits's pamphlet. The word "intensity" was not used in its proper electrical sense. Nothing in the belt could realise the expression that "either intensity or quantity could be obtained." There was no means of coupling up the belt as it was put into his hands. The words implied an impossibility. To connect the belt with a galvanometer, appliances which did not accompany the belt were necessary. If outside connections were on and applied to the galvanometer, you would get no perceptible current because the belt would be short-circuited. There would be an infinitesimal current, but he believed it would be too small to show on the galvanometer. From the description of the experiment it was absolutely certain that the short wires were not connected up. In the third experiment, the current spoken of arose from one formed between the platinum needle and the copper or zinc. A single needle could not tap the current; there must be two needles.

In cross-examination by Sir RICHARD WEBSTER, WITNESS said that what was known as Sir William Thomson's galvanometer was his (Lord Kelvin's) invention. It was an instrument used for testing very mild currents of electricity.

Did not you say, assuming proper connections, that a current would certainly flow through the body, entering the body by the zinc surface and leaving by the copper surface?—Yes, there would certainly be a small current. Whether enough to deflect a galvanometer he had not tried.

You are not a medical man, Lord Kelvin; I believe it is the only attainment you do not possess?—I am an M.D.—(loud laughter)—an honorary M.D. of the University of Heidelberg. I have a license to practice, but I have never exercised it.

Sir RICHARD WEBSTER said he did not dispute Lord Kelvin's evidence, which no doubt, he said, was scientifically correct; and in his view it admitted enough for his case—*i.e.*, a slight current of electricity.

Mr. T. E. GATEHOUSE, part proprietor of the *Electrical Review*, said that neither he nor his partners had any connection with *Science Siftings*. He could take the sole responsibility of the article in question. Witness went on to state that Dr. Tibbits's pamphlet had been sent to the office of the *Electrical Review* "for review," and it was reviewed. He had had no personal knowledge either of Dr. Tibbits or Mr. Harness, and no feeling at all against them. He had read the pamphlet carefully, and had written the review, honestly believing what was stated in it. He had made many experiments upon the belt, and for the purpose of experimenting had purchased several of them. With the belt purchased and produced to-day there were no printed directions, nor had he ever seen or heard of any directions as to connecting the discs.

Sir R. WEBSTER here observed that this was an action by Dr. Tibbits, and so far as Harness was concerned he complained of nothing in the article, and if there were nothing in it reflecting on Dr. Tibbits there was an end of the case; but what he complained of was reflections upon the character of Dr. Tibbits

Mr. BANKES: May I say that the whole system is a fraud.

Sir R. WEBSTER: Certainly not, unless you prove it.

Hosted by Google

Mr. BANKES: Then I am entitled to prove it, and am proving it. He then read from one of the pamphlets that the belts had discs "all connected."

Sir R. WEBSTER: "All connected."

The learned JUDGE pointed out that the belts sold were described as having the discs connected. The article spoke of discs not connected. It would be for the jury to say whether that was a fair criticism on Dr. Tibbits's pamphlet, which spoke of belts with the discs connected.

Examination continued, Witness said he had made tests as to the quantity of electricity produced. The quantity depended on the moisture of the skin of the subject, and he found from one hundredth to one four-hundredth of a milliampere. He should say that there were several paths open for the passage of the current—the surface of the skin, the web of the belt, and the underclothing in contact with the body.

Cross-examined: The action was being defended solely by the defendants. His original position was that practically no electricity could go through the body. Witness explained the working of the Pulvermacher belt, from which he said a current passed to the body.

Mr. HARRY ROBERT KEMPE, one of the defendants, said he had been engaged in the electrical profession 25 years—20 years in the Post Office. He was a member of various societies, and had written standard books on electricity. He agreed with what Lord Kelvin said about the experiments described in Harness's pamphlet. He (witness) had tested the belt. When coupled up, and with the body extremely moist, he had obtained a current of one-tenth of a milliampere. In the ordinary condition it would be one-four hundredth to one-five hundredth of a milliampere. Two to five milliamperes was recognised as the minimum medical dose. After the belt had been worn any time, polarisation would set in, and reduce the current almost to nothing.

Cross-examined by Sir RICHARD WEBSTER: Polarisation would be rubbed off by the action of the body?—No, it would not.

Mr. JAMES SWINBURNE, an electrical engineer whose electrical qualifications Sir Richard Webster said he did not dispute, stated he had seen the pamphlet which the defendants criticised He thought the statements made by Dr. Tibbits showed he had hardly the most elementary acquaintance with electricity, and was therefore incompetent to deal with the subject he wrote about. For instance, it was clear he did not understand the elementary principles underlying batteries. That was proved from his remarks in regard to intensity. The pamphlet also demonstrated that the author did not know how to tap a current. From passages in the pamphlet, he would infer that the belt was not coupled inside or out. He agreed with what Lord Kelvin said as to that, entirely. He agreed with Mr. Gatehouse, that in respect of these belts the current going through the body was practically non-existent.

Cross-examined by Sir RICHARD WEBSTER: He was never of opinion that no current would pass through the body.

Prof. SILVANUS P. THOMPSON said he had examined several of the Harness belts—some with couplings or connections, some without. With those without connections there were no "currents" at all, and with the others very small. It was not possible to connect the discs in these belts so as to produce much effect. The quantity of electricity generated would be infinitesimal. He should call it an infinitesimal current, considerably less than one could obtain by taking a needle and a pin, connecting them together, and dipping them into a drop of ink. Having read Dr. Tibbits's pamphlet, he should say of it, "The dear old doctor did not know what he was writing about."

Sir R. WEBSTER: And that would not have been a libel.

Mr. WALTON: It is very much like what we wrote—that it showed "ignorance of the laws of electricity."

Dr. ARMAND DE WATTEVILLE, who had made a study of the medical effect of electricity, stated that he had examined these Harness belts, and thought that without outside connections there would be no current, and that it would be of no therapeutic value. It would practically be nil if the skin were dry.

Dr. LEWIS JONES, a physician, who had written on medical therapeutics and taught the subject at one of the London hospitals, stated that he quite agreed with Lord Kelvin. He stated the smallest strength of an electric current which would produce any therapeutic effect.

Sir R. WEBSTER objected that this was irrelevant.

WITNESS stated that everything depended upon time; and he stated the remarkable fact that the quantity of electricity passed through the body during ten minutes—the ordinary duration of medical treatment—if passed through the body at once, would be instantly fatal.

Sir R. WEBSTER said he objected to evidence as to the therapeutic value of these belts, as evidence he had offered upon it had been rejected.

Mr. de TUNZELMANN gave it as his opinion that these belts produced no perceptible current—none of any appreciable value. Looking at Dr. Tibbits's pamphlet he should say that he had no electrical knowledge.

In cross-examination he said he had written on the subject in *Science Siftings*. Mr. Harness had brought an action against the publisher, but not for witness's article.

In cross-examination, he said that with connections there would be a current through the body, though, he added, very slight—a mere trace.

Mr. JOHN GRAY and Mr. SEGUNDO gave evidence. None of the last witnesses were cross-examined.

Mr. WALTON, in reply, said that in the first place, an advertisement had been put in evidence which showed the nature and character of the belts as they were being sold to the public. The defendants had to defend their description of the belt and their criticism from the pamphlet. It was clear that the belt Dr. Tibbits operated upon was without outside metallic connections. Sir Richard Webster had had ample opportunity of showing that these belts were supplied with these outside connections, but he had not done that, and he had even failed to show that the public were in a position to know what the connections were for. If the sockets on the belts were not intended for the purpose of coupling with batteries, why was the connecting wire not permanently fixed on instead of being left loose? The defendants assumed, and he asked them to assume, that without connections was the ordinary method in which these belts were supplied to the public. What was the electrical result which these people got for their five guineas? It could only be detected by an extremely sensitive galvanometer, and was not equal to that produced by a needle connected with a pin and dipped into a drop of ink. What was the position the defendants took up? They had not referred rudely nor too severely to Dr. Tibbits. They had hit at the appliance and the sale of a trumpery article, and the man they wished to draw into that Court was the man who had thought it convenient to keep in the background and out of the witness box, and to put forward Dr. Tibbits to fight "the battle of the belt." The plaintiff was responsible for lending his name for forwarding the sale of an invention which the defendants had good grounds for saying had absolutely no value, and said they thought it was a case for the intervention of the medical authorities, to prevent the sale of a worthless article. He (the learned counsel) trusted the jury would find his clients had not exceeded the right which, so long as it was exercised honestly, was a valuable privilege to all of them—namely, that of bold and free criticism—and that they would not by their verdict allow Mr. Harness to get an advertisement out of this matter, when Dr. Tibbits's loss (if any) at the most, could be counted by farthings. In the circumstances, he asked the jury to return a verdict for the defendants on the grounds he had stated.

The Court adjourned.

FRIDAY, FEBRUARY 17TH.

The hearing of this action was resumed.

Sir RICHARD WEBSTER, Q.C., in addressing the jury on behalf of the plaintiff, said his duty to his client, having regard to the extraordinary way this case had been conducted, rendered it necessary that he should bring their minds back to the real issue in the case. Might he say once and for all that he was not appearing there for Mr. Harness; he had nothing to do with Mr. Harness—he appeared for Dr. Tibbits. No doubt the case had been conducted according to the instructions given to his learned friend, but he (Sir Richard) desired the jury to understand that it was no part of his case, as representing Dr. Tibbits, to criticise or comment upon anything the defendants might have said of Mr. Harness. They knew that there were other proceedings pending with regard to earlier articles, and it would be—subject to what his lordship would tell them—a very great injustice indeed if, under cover of defending this action, the defendants should be allowed to turn the articles in question into an attack upon Mr. Harness, instead of what he would undertake to show it was, an attack upon Dr. Tibbits. For when the libel came to be examined and regarded by fair-minded men, he would point out that there was scarcely a word, scarcely a sentence, which was even libellous or slanderous upon Mr. Harness; the whole sting of the article was directed against Dr. Tibbits and against the medical profession as distinguished from Mr. Harness Prior to the end of 1892 Dr. Tibbits did not believe in the possibility of these weak currents going through the body. Dr. Tibbits had published in a series of medical works a statement to this effect as recently as 1888. The jury had seen Dr. Tibbits in the box and heard his evidence, and in justice to Dr. Tibbits he must point out (his lordship observed it at the time) that Dr. Tibbits, having stated that he declined to investigate the matter at all unless his report was accepted by Mr. Harness as it stood, there was no single word of cross-examination with regard to that. He (Sir Richard) had been twitted with not having called Mr. Harness; but if he had done so, not only would he have been wrong, but the evidence would have been irrelevant. Dr. Tibbits claimed to have demonstrated to his own satisfaction that currents did pass through the body, not in the sense of going from side to side of the body, though he daresay they did that (for, as his lordship said on the previous day, if the current got under the skin nobody knew what became of it), but through other parts; and whatever Mr. Gatehouse might have said, that was the statement which was proved to be true by the simple admissions of Lord Kelvin and the other electricians who had been called; whether that fact was of value or not, attention should be drawn to a further point. Dr. Tibbits had been held up to opprobrium because he circulated or allowed this report to be published without pledging his opinion to the medical value of these currents. It would have been in his favour if he could have said that they were useful from a medical point of view, but, fortunately, Dr. Tibbits did not require to eke out his case by any expression of knowledge of the practical working of these belts before proper tests had been made. Accordingly he said, "I have not had sufficient experience of these matters to say whether or not they are therapeutically of medical value." The facts he was going to read were those deposed to by Lord Kelvin. There could be no controversy that Lord Kelvin, from the great pinnacle of his scientific position, put exactly what Dr. Tibbits, with lesser electrical knowledge, and after five or six weeks of experiment, had discovered, and had told in his report which the defendants had before them. Lord Kelvin was asked, "If the belt were placed on a human body in a state of perspiration, and metallically connected, would a current flow?—Yes, a small current would flow." Mr. Walton actually went the length of saying that the defendants came into Court supposing they were going to attack nothing but uncoupled-up belts. Unfortunately, they called a perfectly respectable medical gentleman, who produced an old belt. He (Sir Richard) asked to see it, and the witness admitted that there were permanent metallic connections between the zinc and the copper. Accordingly, upon the only Harness belt produced by the defendants, there were the metallic connections which caused, and which were necessary to produce, any electrical effect at all. It did not stop there. If this libel had been to the effect that if the belts had been electrically coupled up there was a small current of no electrical value, he could have understood it. But this libel upon the face of it referred to what Dr. Tibbits had said in connection with a coupled-up belt, and nothing else. When a medical

Hosted by Google

man said, as Dr. Tibbits had done in this very pamphlet, that the doses of these weak currents must stand the test of experiment, and that all he claimed was that these currents went through the body, he (Sir Richard) ventured to think it was unfair to impute to Dr. Tibbits professional misconduct, being party to a fraud, and being guilty of such unprofessional behaviour in this matter as would entitle him, practically, to be spoken of as a man to be driven out from the pale of honourable people and decent society. What was the libel? Whatever might be said about Mr. Harness, the sting and the whole pith of it was against Dr. Tibbits, and not against Mr. Harness. It was an outrage that, under cover of scientific criticism, such aspersions should be made on the honour and conduct of such a man; and he asked, not for vindictive damages, but, the defendants having pleaded the plea of justification, to say that these aspersions on Dr. Tibbits's character never ought to have been made, that there was no justification for them, and by their verdict to give the plaintiff such damages as would re-establish his position in the medical world.

Mr. JUSTICE MATHEW proceeded to sum up the case to the jury. The alleged libel, he said, was a criticism on a pamphlet written by the plaintiff and published by Mr. Harness. The plaintiff alleged that the criticism was libellous. The defendants, however, alleged that their article did not go beyond the bounds of fair criticism. A newspaper writer had no greater privilege in criticism than any other member of the public. A criticism, so long as it gave expression to an honest opinion, and consisted of honest comment, was not actionable, however pungent, however damaging it may be. There was this well-defined line, beyond which a critic might not go unless he was prepared to justify his allegation—he must not attribute unworthy or dishonest motives to the person whose works he was criticising. The plaintiff here alleged that he was charged with being an impostor and an unworthy member of his profession. If the plaintiff's contention was correct, he was entitled to a verdict. The question was not as to the value of Harness's appliance. Prior to the publication of the articles the defendants had asserted that the electric current generated by the Harness belt did not pierce the skin. Mr. Harness alleged that the current did enter and pass through the body. As it appeared to Harness of great importance to prove the correctness of his contention, he communicated with the plaintiff, a man of considerable scientific attainments, who had established a valuable medical and electrical hospital. But the plaintiff had not been so successful in life as he might have hoped, and it was suggested by the defendants that in his position he would be more likely than an independent man to fall in with Harness's views of the merits of these belts. That was a question for the jury to consider. In 1889 Dr. Tibbits expressed an opinion adverse to electrical appliances of similar, though by no means the same, construction. The doctor had given his explanation of this change in opinion, and of the difference between the appliances. It must be remembered, in considering the position of the plaintiff in regard to Harness, that he made it an absolute condition that the report should be accepted, whatever its contents might be. The pamphlet appeared to convey the impression that Dr. Tibbits's opinion was that the belts he examined were useful instruments. In the witness-box Dr. Tibbits declared he had not formed any opinion as to the value from a medical point of view of the belts. It was for the jury to judge whether in the pamphlet the doctor did give expression to such an opinion. It must, however, be noted that the reference to "dosage" in the pamphlet seemed to indicate that the plaintiff intended to carefully limit any opinion which he might have expressed. The first part of the libel referred to the vendors of these articles; the second portion more directly to the plaintiff. It was for the jury to judge whether the criticism went beyond the limits of fair criticism already pointed out. Did it imply that the plaintiff was attempting to dishonestly bolster up appliances which the defendants allege were useless? Again, it was for the jury to determine whether the phrase in which the hope was expressed "that a grave scandal may at last be unveiled in all its grossness and the promoters and abettors brought to book" was or was not fair comment. If the jury thought the article had gone beyond the limit, probably they would think it very close on the line. Sharp, pungent criticism did not make libel. If this was an honest expression of opinion on which honest opinion was challenged by the plaintiff himself, the defendants were entitled to a verdict. Further, it had been dwelt upon that this action was not brought to relieve the character of the plaintiff from any professional stain, but with a view of recommending to the public appliances of which the plaintiff had approved, and from which Mr. Harness was drawing large profits. The jury must consider if it were a question of damage by what figure they marked their sense of any wrong they considered had been done by the defendants to the plaintiff.

The jury having consulted seven minutes returned a verdict for the defendants.

The announcement was received with applause.

Judgment, with costs, was given accordingly.

CORRESPONDENCE.

THE BROWN MOTOR.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: We have the honour to inform you that the new motor described by Mr. Brown in your issue of January 27th last, was invented by us in 1890. You will find a description of it, together with the complete theory, in *La Lumière Electrique* of May 30, 1891, pp. 419—422.

We should be much obliged if you would kindly verify the accuracy of our claim of priority, and to announce it to your readers.

Thanking you in anticipation, we remain yours, &c.,

63, Allée du Jardin Anglais, HUTIN-LEBLANC.
Le Raincy, February 18, 1893.

[As stated last week, in our brief reference to this letter, we have referred to *La Lumière Electrique*, and find an elaborate mathematical dissertation together with illustrations of a 15 kilo-watt motor.—ED. *E*]

USEFUL FORMULÆ.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: The following is a useful rule for rapidly finding the square of any number under 120 without the use of pencil and paper.

Add to, and substract from, the number to be squared a small number a, so that one of the two results becomes a mutiple of ten. Then multiply these two results together and add the square of the small number a. Thus, to square 67—Add and substract 3; then $70 \times 64 + 9 = 4489$.—Yours, &c.,

ALAN WILLIAMS.

21, Shaa-road, East Acton, W., Feb. 22, 1893.

"THAT BLESSED WORD 'INSTALLATION'"!

TO THE EDITOR OF THE ELECTRICIAN.

SIR: We have found this much-abused word most useful here as covering wiring, fittings, lamps, holders and glassware. In many contracts we have arranged to supply the whole "installation" consisting of these items at a fixed price per light, and I do not known what other single word we could have employed.—Yours, &c., L. A. SELBY-BIGGE.

University College, Oxford, Feb. 21, 1893.

SUBSTITUTE FOR PLATINUM.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: We notice your article on p. 46 in last week's issue on the subject of a substitute for platinum wire for incandescent lamps, and it may interest you to know that we manufacture wire under the Langhans patents for many different uses, amongst others for use in sealing into incandescent lamp bulbs. We have had a number of lamps made some eighteen months ago, which have burned from 700 to 800 hours, and in which, on being tested after an interval of twelve months since they were used for lighting purposes, the vacuum still remains perfect. In the manufacture of the wire, in the process of which we have made many important improvements, the difficulties first experienced were in obtaining the proper alloys, and in the platinising process. We find that there is no difficulty in sealing into the ordinary glass, and in special work we can obtain qualities of glass suitable for alloys of our wire, with different expansions.—Yours, &c.,

THE COMPOUND WIRE SYNDICATE,
Feb. 21, 1893. Alfred Riley, Secretary.

NATAL LIGHTNING.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: Attached I send you a cutting from our local paper, the *Natal Advertiser*, the publication of which by you will probably cause your numerous readers a little amusement. I think you will agree with me that Mr. Walter Stead must be

Hosted by Google

a genius of the highest order, and should not any longer be allowed to remain unknown to the leading spirits of the electric world.—Yours, &c., H. J. SEALY.

Durban, January 20, 1893.

[*Extract from the "Natal Advertiser."*]

LIGHTNING ACCIDENT AT NOTTINGHAM ROAD.

CURIOUS BUT SUCCESSFUL TREATMENT.

Last Monday afternoon a rather serious accident occurred at Nottingham Road, which, but for the prompt measures which were taken, might have had a fatal termination. During a heavy thunderstorm Mr. Sam Stead, a well-known and respected farmer in the district, was struck by lightning while standing on one of the front windows of his house, the lightning paralysing one side and rendering him speechless. He entered the house, and conveyed the intimation by signs to his family, who as once took steps to relieve him. Fortunately, Mr. Walter Stead, one of the sons, was at home, and being acquainted with the nature of electricity and its mode of treatment, at once commenced pouring hot and cold water alternately down the side that was affected, following up this treatment by chafing, as the electricity was beginning to draw Mr. Stead's body up. Brandy was administered internally, after which he was able to speak. He was put to bed, while Mr. Walter Stead procured some copper wire, which was utilised as a conductor from the injured man's body out of the window into the ground, and by means of which he obtained speedy relief. We are glad to state that Mr. Stead has now almost completely recovered from the shock. Great credit is due to Mr. Walter Stead for the prompt and effective manner in which he treated the case.

[*Letter to the "Natal Advertiser."*]

A WONDERFUL EXPERIMENT.

SIR,—If the account in to-day's issue of your paper is a correct one, the lightning at Nottingham Road must be of a peculiarly accommodating nature, and different to that experienced in any other part of this sinful world. If, as you say, Mr. Walter Stead is acquainted with the nature of electricity, he must know that, when a man is struck by lightning, the electricity passes through him and goes to earth immediately, and does not, as we are asked to believe, remain in his body, fooling around waiting the advent of some budding genius, anxious to try experiments with a copper wire.

You may take it from me that Mr. Stead's recovery was due to one of two things: either to the administration of brandy, or to the utter astonishment he must have experienced at his son's experiment.

I intend sending the paragraph in question to *The Electrician*. It will, I feel sure, cause Lord Kelvin and others a good laugh, or else send them into a fit—in any case, it will effect something, and that is more than can be said for Mr. Walter Stead's copper wire!—I am, &c., S.

Durban, Jan. 13th, 1893.

TRADE NOTES AND NOTICES.

[*Notices for insertion under the above heading must reach the Office not later than first post Thursday morning. New Catalogues, Price Lists, and similar matter should be sent early in the week.*]

Our readers are reminded that the 1893 Edition of "THE ELECTRICIAN" Electrical Trades' Directory and Handbook is NOW READY. This useful book contains over 1,000 pages, and several new and handy features have been added. The price of the Directory and Handbook is 7s. 6d. Postage in the United Kingdom, 9d.; abroad, 1s. 4d.

TENDERS INVITED.—The Bristol Urban Sanitary Authority invite tenders for the supply, delivery, and erection of switchboards, terminal bars, transformers, and other articles for their central electric lighting station and sub-stations. Specifications, &c., can be obtained of Mr. D. Travers Burges, the town clerk, 51, Prince-street, Bristol. Tenders must be in by March 15th.

——— The Corporation of Huddersfield invite tenders for the supply of main switches and main fuses for controlling the supply of electrical energy to consumers' premises. Samples and tenders to reach Mr. A. B. Mountain, borough electrical engineer, Gasworks-street, Huddersfield, not later than March 15th.

——— Electric light companies are invited to furnish to the Portrush Town Commissioners, on or before March 1st, statements of the terms upon which they would be prepared to undertake the public lighting of the town of Portrush by electric light.

TENDERS ACCEPTED.—Messrs. Laing, Wharton, and Down have secured the contract for electric wiring and supply of fittings to Messrs. Stubbs and Co.'s offices at 42, Gresham-street, E.C.

——— The tender of Messrs. S. Dixon and Sons, of Leeds, has been accepted for the lighting of the *Yorkshire Post* office and works. The installation will consist of about 400 lights.

SALE BY AUCTION.—The sale by auction by Messrs. Wheatley Kirk, Price and Goulty of the contents of the Plashet Hall Works, Forest Gate, E., comprising electric motor tramcars, dynamos, engines, machines, tools, electric fittings, &c., will take place, as will be seen from our advertisement columns, on March 8th.

——— Messrs. Edward Rushton and Son, of 13, Norfolk-street, Manchester, and 21, Richmond-terrace, Blackburn, notify the piecemeal sale of a valuable electric lighting plant, portable engines, &c., recently in use by the National Electric Supply Company (Limited), of Preston, Lancashire. The sale will take place on Wednesday, the 1st prox., at Strand-road, Preston, and includes engines, boilers, dynamos, and a quantity of copper cable and electrical apparatus, comprising a complete installation. Further particulars are given in our advertisement columns.

——— Messrs. F. J. Bisley and Sons announce that they will sell by auction, at 89, Union-road, Rotherhithe, S.E., on March 2nd, at 12, for 1, the stock and plant of an electrical engineer, comprising electric light fittings, batteries, copper wire, switches, bell pushes, tools, and miscellaneous effects.

APPOINTMENTS VACANT.—An assistant telegraph superintendent is required for India. Particulars are given in our advertisement columns, and applications in writing must be sent to Mr. G. Berkley, 57, Charing-cross, London, S.W., from whom all further particulars can be obtained.

——— The County Asylum at Lancaster require an electrician to take charge of a 300-light plant, who is also competent to look after the telephones and electric tell-tales. Other particulars are given in our advertisement columns, and application should be made to the Medical Superintendent of the County Asylum, Lancaster.

THE INTERNATIONAL ELECTRIC COMPANY (34, ALDERMANBURY, E.C.).—This Company have just been appointed sole agents for the United Kingdom by the Helios Company, of Cologne, for the sale of their direct and alternating current arc lamps, which, it will be remembered, obtained special mention at the Frankfort Electrical Exhibition.

LONDON ELECTRIC SUPPLY COMPANY.—In order to dispel the idea that high-pressure supply by alternating currents is dangerous, this Corporation is issuing a circular with some very clear diagrams printed in colours, showing the complete distinction between the high-pressure circuits and those which enter the houses of the consumers.

NATIONAL WORKMAN'S EXHIBITION.—Mr. J. G. Lorrain sends us some printed matter relating to the National Workman's Exhibition, which is to be held at the Agricultural Hall, Islington, London, N., during June, July, and August. The prospectus states that the aim of the promoters of this exhibition is to confine the exhibits to the highest-class skill of our artizans, mechanics, and apprentices. It is intended to afford workpeople of both sexes an opportunity of proving their inventive capacity, and is intended to be an effort towards arresting the growing disregard for good work which is only too plainly apparent in many departments of trade and manufacture in this country. The exhibition has received the support of the London Trades Council, the Lord Mayor of London, the City Corporation and Guilds, and should, we think, find many supporters in the electrical and allied trades. It is to be hoped that the Exhibition will not generate into a mere show by shopkeepers, and that, under the special patronage which it will receive, an effort will be made to include in the exhibits only such work as can be legitimately placed to the credit of the actual workman. Amongst the executive committee are the names of several leaders of workmen's associations, but we hope to find in a later list the names of the leading employers in a number of trades which it is only reasonable to suppose may be distinctly affected by the exhibits shown.

BANKRUPTCY NOTICES.—Claims against the estate of James Collins, of 80, Church-road, Hove, electrical engineer, are to be sent in by March 7th to Mr. R. J. Ward, 7, Pavilion-buildings, Brighton.——The discharge of Victor Silberberg, who traded at 47, Oxford-street, W., as the Electrical Fittings Manufacturing Company, has been suspended for two years.

CREDITORS' MEETING.—The meeting of the creditors of Mr. F. Silvester, of Newcastle-under-Lyne, trading as Fred. Silvester and Co., was held at Stoke-on-Trent, on Friday last, at which it was resolved that a circular should be sent to the creditors to ascertain whether they would consent to a deed of assignment of all his effects to a trustee for the general benefit of the creditors.

BACUP.—At the last meeting of the Tradesmen's Association a discussion arose on the subject of the introduction of the electric light, and as to whether the time had now come when this should be attempted. Mr. Priestley made a long statement on the sub-

Hosted by Google

ject, advising the members of the association not to push the matter at present, but to wait until the lamp royalties expired. This course was supported by the Chairman, Councillor Salmon, and was ultimately adopted.

BATAVIA EXHIBITION.—*The Engineer* of the 17th inst. contains particulars of the exhibition to be held in the Dutch colony of Batavia, in August, September and October of the current year. Amongst the exhibits, which it is stated will be likely to be profitably shown, are included steam, gas and petroleum motors, water-wheels and turbines, light and portable railway plant, mining machinery, and apparatus for electric lighting, which is coming into favour in the colony. It is suggested that a 300 16-c.p. plant would be a saleable one at the close of the exhibition, and that smaller installations should also be sent, the price of gas being high in the colony. Applications for space should leave this country not later than April 14th, and offers for the supply of power, or for electric lighting, should be sent immediately. All exhibits have to be delivered at the Port of Batavia before June 30th. Machinery and other implements are admitted free of duty, and also the transport of exhibits in the colony, both by rail and local steamers, will be free of charge. The export steamers from Europe will carry goods for the exhibition at the usual rates; but goods unsold, or not otherwise disposed of, will be brought back to this country free of cost. Messrs. John Birch and Co., of 10 and 11, Queen Street-place, E.C., will supply further information, and render assistance to intending exhibitors.

BERWICK.—The Lighting Committee of the Town Council have in preparation a scheme for the electric lighting of the Borough.

COMMISSIONERS OF SEWERS (LONDON).—At the last meeting of the Commissioners an account was submitted from the City of London Electric Lighting Company, and passed, for lighting the public streets of the City up to December last, the amount being £4,213. The Commissioners resolved to advance certain objections to the National Telephone Company's Bill now before Parliament.

MESSRS. CROMPTON AND CO. (LIMITED).—Considerable interest was taken in the assortment of new electric heating apparatus, which was shown at the President's reception at the Institution of Civil Engineers on Tuesday last. The apparatus was shown working, and it was generally admitted that Messrs. Crompton and Co. had brought the application of electric heating to a very advanced stage. A large number of orders are being received for electric ovens, and the firm have quite a difficulty in meeting the orders for their other apparatus, which are coming in from all parts of this country and abroad.

EALING.—The Local Board have received the report of Messrs. Bramwell and Harris as to the best means of lighting Ealing by electricity. The Chairman moved that the report be printed and circulated amongst the members, and this suggestion was adopted. He stated that from the report it was clear that the electric lighting of Ealing was quite possible, and resolved itself merely into a question as to the amount of support they were likely to get from the ratepayers. Another member of the Board thought the ratepayers would appreciate the report. Instead of having to pay for power they would have the effluent water and the heat of the destructor at their service, and if the works were well managed he did not see why the whole concern should not result in profit to the ratepayers.

EDINBURGH.—It appears that after appointing a deputation to visit the chief electric lighting stations throughout the country, the Town Council of Edinburgh will not, after all, undertake the electric lighting of the town, owing to agreements with the Gas Commission. At their last meeting it was ultimately decided to remit to the Lord Provost's Committee to consider and report as to whether the powers under the Electric Lighting Provisional Order, 1891, should or should not be transferred to the Edinburgh and Leith Town Commissioners. Councillor Anderson, who proposed that this step should be taken, stated that if the Council supplied the electric light it would come into direct conflict with the Gas Commission, and if they gave the work to a local company they would be acting in violation of their arrangement with the Commission.——The Town Council have under consideration the introduction of the electric light at their destructor premises at Powder-hall, and have decided to consult Mr. Murray with the object of receiving from him a report on the subject.

ELECTRO-HARMONIC SOCIETY.—This (Friday) evening, in the Banquet Room, St. James's Hall, Regent-street, W., a "Ladies' Night" Concert will be held, under the direction of Messrs. Gatehouse and Izard.

THE ELECTRIC LIGHT FOR PUBLISHING OFFICES.—Messrs. Lowdon Brothers, of Dundee, have just completed an installation of the electric light in the editorial and publishing offices of the *Dundee Advertiser*.

HARROGATE.—The sub-committee appointed by the Town Council to consider the subject of electric lighting has presented its report, in which they recommend the Council to transfer to a company the powers, duties, and liabilities undertaken under the Electric Lighting Provisional Order of 1891. A long discussion on the subject ensued, and a resolution was carried that the Council apply to the Board of Trade for an extension of time, in order that negotiations may be entered into for the purpose of making satisfactory arrangements for the transference of the Council's powers to a Company.

HUDDERSFIELD.—The engineer and house surgeon of the Huddersfield Infirmary have been instructed by the County Council to visit London for the object of inspecting the systems of lighting adopted in the various hospitals here. Satisfactory progress is reported with the public lighting of the town.

HYTHE AND SANDGATE.—Negotiations are pending with the South-Eastern Railway Company for the supply of electric power for the tramway between Sandgate and Hythe, the power also being used for lighting the Parade from Sandgate and Seabrook to Hythe.

LIVERPOOL.—The City Council have given permission for the Liverpool Electric Supply Company to lay their mains through Sefton Park, in order to enable the Company to supply the adjoining districts with the electric light.

MALTON.—The electric light has been introduced for the first time in Malton (Yorkshire), at the works of the Farmers' Manure and Trading Company (Limited). This Company was the largest consumer of gas in the town, and has now started to make its own gas on the Dowson principle for use with the gas engines employed in the generating plant. Messrs. Parr and Gillies have put down the plant, which included, at the ceremony of turning on the light for the first time on Saturday last, a search light of 100,000 c.p., brought into play from the top of the mill, to the considerable astonishment of the natives.

THE MILITARY SEARCH LIGHT.—Speaking at the annual dinner of the 4th Middlesex Volunteers, Captain Ronald Scott, who commands the F Company, referred to a new type of waggon designed for transporting the search light apparatus with which his name is associated. He announced that he had been in consultation with the Horse Guards, and that within a short period the light would be tested as to its capability for use in night attacks on a large scale.

MORECAMBE.—The plans submitted by the Morecambe Electric Light and Power Company (Limited), for the proposed lighting of the front, has been approved by the Local Board.

NEWCASTLE.—At a meeting of the City Lighting Committee of the Corporation on Tuesday a deputation of merchants was heard on the subject of introducing the electric light into the principal thoroughfares. A motion was unanimously adopted that a meeting be held to consider the advisability of the Corporation taking up the electric lighting on its own account.

NEW TELEPHONE COMPANY (LIMITED).—We have received from Manchester the new list of subscribers to the New Telephone Company, which is in slip form. The present list shows a considerable augmentation of members over the list previously issued by the Company, and includes the subscribers to the Bolton and Radcliffe and Eccles and Penderton exchanges. We think the list would be handier in book form.

PRIVATE LIGHTING.—Mr. Francis Ricardo, of the Friary, Old Windsor, possesses an electric light installation, possessing some special features of interest. The estate is an extensive one; and the lighting mains have to pass under the public road, and under a portion of the estate from the engine-house to the mansion. Messrs. Edmundson were the contractors for the installation, which comprises a Davey-Paxman "loco" type boiler of 12 H.P. nominal, double cylinder Davey-Paxman engines, and an Elwell-Parker shunt-wound dynamo, capable of giving 80 amperes at 180 volts. The lamps supplied represent 230 16-c.p. lamps (a few being 32's), and are lighted at the exceptional pressure, for a private installation, of 135 volts. Under ordinary circumstances the light is supplied through E.P.S. L type accumulators, which have a total capacity of 450 ampere hours. Besides the private house installation, Mr. Ricardo owns an electric launch, for charging which a separate cable is carried beneath the high road to the river-side. This craft is 40ft. long with a 7ft. beam, and is fitted with 58 15-plate E.P.S. cells (1888 L type), and an Immisch motor. Running at full-speed the launch can cover about seven miles an hour, and five miles at half-speed with the cells in parallel.

RICHMOND, SURREY.—The Town Council have been in communication with Messrs. Latimer Clark, Muirhead, and Co., Limited (who are contractors with the Corporation for the electric lighting of the town), and have arranged with that Company for the lighting of the Town Hall, the work to be completed by the first week in May next.

Hosted by Google

ROMNEY.—The Lighting Committee has been enlarged by the addition of two members, and will meet next week to discuss the question of the electric light with the Directors of the Gas Company.

ROTHESAY.—The Harbour Trust and Town Council have had under discussion their electric lighting scheme. Messrs. Mavor and Coulson, it will be remembered, reported on this question some time back, and the matter now in doubt was whether the Trust had water power enough for a turbine wheel plant, this being recommended on economic grounds by Mr. Milloy, the Chairman of the Electric Lighting Committee. It was ultimately decided to obtain another engineer's report, either to confirm or otherwise the report previously received.

ST. HELENS.—At the meeting of the County Borough Council last week, the Surveyor submitted his report dealing with the subject of the supply of electricity to the Town Hall and offices, which showed an increased cost over the charge made for gas the previous year, which was, however, explained by the fact that the light had been burning a considerably longer period and with better effect. The Surveyor has calculated that the cost of generating the light represented gas at 2s. 11d. per 1,000 cubic feet, the cost per unit of electricity being 3·47d.

SYDNEY (N.S.W.)—It is announced that the installation of the electric light in the City of Sydney will be carried as a municipal scheme during the current year. The City Council have a Bill before Parliament giving them the necessary powers for undertaking the public lighting, and also supplying private consumers, although it is not yet definitely known whether the matter will be ultimately transferred to a private company.

WEYBRIDGE.—A letter from the Laing, Wharton and Down Construction Syndicate (Limited), announces that the syndicate have transferred the whole of their Weybridge undertaking to the local electric light company as from the 1st January last. The syndicate were under an engagement to remove the existing overhead wires, and the matter is now receiving the consideration of the Weybridge Company. The work of placing the wires underground will, the letter states, be commenced at an early date.

PATENT RECORD.

A record of Applications for Patents and Patent Specifications Published is compiled for this journal by MR. J. C. CHAPMAN, *Fel. Chartered Inst. Patent Agents, of 70, Chancery-lane, W.C., from whom any information on the subject may be obtained.*

APPLICATIONS FOR PATENTS.

NOTE.—*The Specifications of Applications for Patents are not open to public inspection until after the acceptance of the complete specification. The names within parentheses are those of communicators of inventions, or where complete specification accompanies application an asterisk is suffixed.*

COMPANIES' MEETINGS & REPORTS.

Cuba Submarine Telegraph Company (Limited).

The forty-third ordinary general meeting of the Cuba Submarine Telegraph Company (Limited) was held at their offices, 58, Old Broad-street, on Wednesday, February 22, 1893, to receive the Directors' report and accounts for the half-year to December 31, 1892, and to transact the other general business of the Company. The chair was taken by Mr. Charles W. Parish.

The CHAIRMAN: Gentlemen, I will ask the Secretary to read the notice calling the meeting.

The SECRETARY (Mr. James Scott) having read the notice,

The CHAIRMAN said: Will you take the report as read, gentlemen? It has been in your hands for some days, and I presume you will not wish to listen to it again. (A voice: Take it as read.) I am very sorry to have to tell you that our Chairman is unwell, and is therefore unable to attend our meeting to-day. He has not been well for some little time, but he is now better, and had fully hoped to be able to address you this morning. Unfortunately, however, he has had to send us word that he cannot come. I know you will join with us in expressing regret at this occurrence, and in wishing Mr. Greenwood a speedy and complete recovery. (Hear, hear.) It is with great pleasure that your Board ask your approval and acceptance of the report and accounts, and which cover the period of six months from July 1st, 1892, to December 31st last. Happily, we have had no interruptions in our traffic, and we have thus been able to carry quickly and accurately a large volume of business, which must be not only satisfactory to the public whom we serve, and to the Companies with whom we work, but also, I am sure, to our shareholders. It has been a wise custom at these half-yearly meetings to compare the results of the six months working with the corresponding period of the previous twelve months, for you will understand that conditions of business in the West Indies are naturally more uniform at certain seasons of the year, and so more useful for comparison. Following this custom I will now offer you a few remarks comparing the last six months of 1892 with those of 1891. It is with great satisfaction that we can point out an increase of traffic receipts of over £700. In 1891 we earned £19,362. 12s. 9d., while last year, as you will see from the accounts before you, the figure reached no less than £20,089. 2s. 8d., and it is an especially favourable result when you notice that there has been an actual reduction in our working charges of £235. 4s. 5d. In looking more closely at these costs we find under London office expenses an item of £47. 14s. for travelling expenses which did not occur in 1891, and I would mention that this arose from a special journey to Madrid undertaken by Mr. Keith. But under the station expenses, there is a saving in salaries and wages, and also in the maintenance of the land lines, while there is an increase of travelling expenses from some changes in our staff. You will recollect that at our last meeting, held in August, our Chairman mentioned that we hoped to clear off under date of December 31st last the remaining balance of the £48,000, which, as you are aware, has been charged to revenue for the Cienfuegos-Santiago 1881 cable. The exact amount of this balance was £497. 4s. 9d., and this, with the usual half-yearly charge of £1 875, makes up the £2,372. 4s. 9d., which figures in the accounts before you—to the debit of revenue, of course. You doubtless are all aware of the failure of the New Oriental Bank, with which the Company has a deposit of £3,000, and as there are grounds for fearing the liquidation of this unfortunate bank may not be satisfactory, your Board has charged the half-year's profits, with £1,500 as a reserve, against any loss we may have to sustain. I have good reason for supposing it will not be such a large amount as that. We have been able to carry £4,500 to the reserve fund, which now amounts to the very respectable sum of £94,500. Mr. Keith is unavoidably absent to-day, for he is in Cuba, as mentioned in the report; but we expect he will be home again in three or four weeks, leaving everything in thorough good working order. I do not know whether there are any other points of interest to mention, but perhaps some proprietors may like to put some questions. With your permission I will now move:—

"*That the report and accounts for the half-year ended December 31st last, now submitted, be received and adopted.*"

Mr. ALEXANDER F. LOW: I have much pleasure in seconding that.

A SHAREHOLDER: Do you think that the £1,500 you mentioned is sufficient to cover the loss you may have through the New Oriental Bank?

The CHAIRMAN: Yes, sir. The Board believe it will be fully sufficient; indeed, I may mention that we have good authority for expecting a better dividend than we are now allowing for.

Some discussion followed as to the investments, after which the Chairman moved, and it was carried unanimously:—

"*That the following dividends for the half-year be now declared upon the shares of the Company, viz., at the rate of 10 per cent. per annum, subject to income tax, on the preference shares and 8 per cent. per annum free of income tax, on the ordinary shares, payable on and after to-morrow.*"

Mr. LOW: I beg to second that.

The resolution was carried unanimously.

The CHAIRMAN: I think that is all our business to-day, and I am much obliged to you for your attendance.

A vote of thanks to the Chairman and Directors terminated the meeting.

The following is the report of the Directors:—

"From the balance-sheet and accounts for the half-year ended 31st December last it will be seen that the gross receipts (including the balance brought from last account) amount to £22,850. 15s., and the gross expenditure (including the balance of the contract price of the 1881 cable) to £6,972. 16s. 4d., leaving a sum of £15,877. 18s. 8d. to the credit of revenue account. Of this the sum of £1,500 has been set aside as a reserve against any loss from the deposit with the New Oriental Bank Corporation, which is now in liquidation, and £4,500 added to the reserve fund, making that fund £94,500. The dividend on the preference shares will absorb £3,000, and leave £6,877. 18s. 8d., out of which the Directors recommend the payment of a dividend on the ordinary shares at the rate of 8 per cent. per annum, free of income tax, the balance, £477. 18s. 8d., being carried forward to the current half-year's account.

"The main cables have continued in good order throughout the half-year, but the harbour lengths at Cienfuegos and Santiago have been interrupted. Three new lengths, one at Cienfuegos and two at Santiago, have been laid by Mr. Keith since the end of the year. The cost of this work and of the repairs to the old lengths will appear in the accounts for the half-year to 30th June next.

"A little progress has been made in the Company's suit against the Spanish Government at Madrid. The Government has issued a Royal Order for the verification by the Cuban authorities of certain points raised in the case."

Westminster Electric Supply Corporation (Limited).

The ordinary general meeting of the shareholders of the Westminster Electric Supply Corporation (Limited) was held at the Corporation's offices, Eccleston-place, Eccleston-street, Belgravia, S.W., on Wednesday last, the Right Hon. Lord Suffield, K.C.B., presiding.

The SECRETARY (Mr. Frank Iago) having read the notice convening the meeting,

The CHAIRMAN said: Gentlemen, I presume that as a copy of the report and accounts has been sent to each shareholder, you will allow them to be taken as read. [Taken as read.] In moving the adoption of the report I take the opportunity of congratulating you on the fact that the Corporation has reached the position of a dividend-paying concern. You will see from the accounts that the net earnings of the past year have been £8,656. 8s. 1d. to which must be added £3,159. 14s. 3d. brought forward from 1891, making £11,816. 2s. 4d. at credit of net revenue. Out of this the Directors have paid an interim dividend at the rate of 3 per cent. per annum for the half-year ended June 30, 1892; and they now recommend the payment of a dividend at the rate of 4 per cent. per annum for the past half-year, carrying forward a substantial sum to 1893. The Directors feel, and I am sure you will agree with them, that the aim of the Corporation should not be to pay large dividends at first, but rather to build up the business on a sound basis, at the same time paying to the shareholders a fair dividend out of the profits of the undertaking. We have written off all bad debts, which are very small, a proportional part of the preliminary expenses and suspense account; and depreciation of plant, buildings, and furniture, and no sum fairly chargeable to the revenue of the year has been carried to capital or suspense account. You will observe that the depreciation of plant has been fixed at £2,500 for 1892, and this the Directors consider to be a fair amount, looking at the fact that some of it was not ready for use at the beginning of 1892, to the efficient state in which the plant has been maintained, and the expenditure for all repairs and maintenance which has been charged to revenue exclusively. The whole of the plant has worked thoroughly well during the past year, and the stations for generating the supply are well equipped and working most satisfactorily. When we had the pleasure of meeting you last, attention was drawn to the fact that for the two last quarters of the year 1891 the cost per unit had shown a great decrease in comparison with the preceding periods, and you will be glad to learn that for the year ending December 31st last the expenditure under this head shows a still greater economy. You will notice that we now have mains laid in 33 miles of roadway, equal to about 130 miles of ways, and, practically, the whole of the principal streets in our area have been laid, with the exception of the streets now being rebuilt on the Duke of Westminster's estate in Mayfair. The principle adopted by the Directors is not to lay a main in any street not already provided for, unless they see the prospect of a good percentage on the capital expenditure, a policy which has resulted in the whole of the capital expended in the streets earning a fair profit. Owing to the unexpected number of lights applied for it became necessary to raise more capital, and the Directors therefore carried out the promise made at the last general meeting, and offered an additional amount of £40,600, in £100 debentures, to the then existing shareholders. Owing to the progress made by the Corporation they were enabled to do this at a reduced interest, 4½ per cent. per annum, instead of the original rate of 5 per cent., and the whole of this issue was at once taken up by the shareholders. Some idea of the advance of the business may be gathered from the fact that whereas on December 31, 1891, the electric energy supplied was equivalent to 62,820 lamps of 8-c.p., on December 31, 1892, the number had increased to 98,686, while at the time the report was printed the equivalent of 102,743 lamps of 8-c.p. were on circuit, and applications were in hand for a further 8,229, the applications still continuing at a considerable rate. You will be gratified to learn that in addition to the numbers already given the Corporation have been requested to provide for supply to Her Majesty's Foreign Office, which we hope will be followed by the other large Government offices situated at Whitehall. I am not aware of the exact number likely to be installed, but I know it will eventually be very considerable, and we are already prepared to supply. The installation at the Houses of Parliament has also been largely increased by the connection of the current to the House of Lords. I must now refer to the reduction which your Directors have already made, and are about to make, in the standard charge per unit. In June last, after very careful consideration, they came to the conclusion that it was advisable to reduce the price from 8d. per unit, allowed by the Provisional Order, to 7d. I think I am right in saying that the Westminster Corporation was the first Supply Corporation in London to voluntarily reduce the standard charge to their consumers, and experience has already shown us that it was a wise

Hosted by Google

policy to adopt. Not only has it created a good feeling among the consumers who were then on circuit, but it has, we feel sure, greatly increased the number of applicants for current, and it was found that when the reduction was made many consumers added to their existing installations. The Directors have lately again had this matter under consideration, and they feel the time has now come when they must be prepared, in justice to the consumers, and without injury to the shareholders, to still further reduce the charge. They have, therefore, issued a circular to their consumers, and to all residents throughout the area of supply, stating their intention to still further reduce the standard charge to 6d. per unit from March 31st next, with a sliding scale of rebates to very large consumers. They feel confident that by dealing thus liberally with their consumers they will not only retain their present customers, but so largely increase the number of applicants as to be able to earn a much larger net revenue than if they held to the present charge of supply. I will not further detain you, except to say that while we, your Directors, have all given our best attention to the concerns of the Corporation, we, and you, are greatly indebted to an excellent staff for the success of the undertaking. The engineer-in-chief, Prof. Kennedy, with untiring zeal and his large experience, has proved invaluable, and has, by his forethought and great care, succeeded in supplying current with the utmost regularity, as to which no cause for complaint has ever arisen. Our manager, Captain Bax, has in all respects given us complete satisfaction, as has also our secretary, Mr. Iago. I must congratulate you, as shareholders in the Westminster Electric Light Supply Corporation, on having sailed out of troubled waters into a secure position. What with competition, rivalry of a strong company (which, to put it mildly, has left no stone unturned to their own advantage), and difficulties of many kinds, it is something to say, notwithstanding, that we find ourselves, after writing off a considerable sum (which, as prudent men of business, we have considered advisable) by way of reserve, and carrying over a substantial sum to the next account, enabled to offer a 4 per cent. dividend for the last half-year, and considering what I have stated as to the very large increase of current which we are prepared now to supply, it is not too much to say that we may hope to add to this dividend before long. I now formally move the adoption of the report and accounts.

Mr. JAMES HESLOP POWELL in seconding the motion, supplemented the remarks of the Chairman by explaining by means of a chart, the area which the corporation supplies, the progress it has made since its inception and its expenditure in proportion to its income.

Mr. FITCH said that he observed that the charges for generation and distribution were 43 per cent. of the net receipts, while those for another company in which he was interested amounted to 33 per cent., or a difference against this Company of 10 per cent. Another company (the Strand company) worked at 40 per cent. of its net income. He hoped that as their income increased they would be able to reduce the working cost.

The CHAIRMAN said that he had already referred to the increased economy likely to be effected, and their chief engineer, Prof. Kennedy, would say something on the subject.

Mr. FITCH said he merely wished to draw attention to the fact, but in no hostile spirit.

Prof. KENNEDY said that he was very glad that anyone should analyse the accounts, for the more these were critised the better. Mr. Fitch's remarks were perfectly correct. The St. James' Company generated practically the same number of units, but every lamp took double the amount of current per annum. In spite of that fact he thought that the Corporation were really doing better, because their district was five times as large as that of the other, with, at present, the same output. He would venture just to give the comparison between their first and second month's experience this year. In the first six months the Corporation had sold 560,000 units, and the total cost had amounted to £6,890; whereas, in the second period, they had sold 660,000 units, their total expenses having amounted to £6,750, or 100,000 more units at an outlay of £160 less.

The CHAIRMAN then put the motion to the meeting, and declared it carried. He afterwards moved the declaration of a dividend at the rate of 4 per cent. per annum, payable on March 1st next.

Mr. R. W. WALLACE seconded the motion, which was carried unanimously.

The CHAIRMAN said that he had great pleasure in moving the re-election of Mr. J. Browne Martin to his seat at the Board.

Mr. COOPER seconded the resolution, which was agreed to *nem. con.*

Mr. W. HAYES FISHER, M.P., next proposed the re-election of Mr. Wallace, the other Director retiring by rotation, remarking that Mr. Wallace's technical knowledge and legal experience had proved invaluable to the Board.

Sir MARK J. STEWART, Bart., seconded the motion, which was carried unanimously.

Mr. MARTIN and Mr. WALLACE expressed their acknowledgments, the former observing that he agreed with Mr. Fitch that the reduction of the price of the electric light which the Corporation had made, and the expiry of the Edison and Swan patents, would lead to a great consumption of the illuminant, and, consequently, increased dividends to the shareholders.

Mr. T. S. SCRIMGEOUR proposed and Mr. TROLLOPE seconded the reappointment of the auditors, Messrs. Cooper Bros. and Co., which was agreed to unanimously.

Sir MARK J. STEWART then proposed a vote of thanks to the Chairman and his colleagues for their able conduct of the business of the Corporation.

The CHAIRMAN in expressing his acknowledgment paid a warm tribute to the interest taken in the Corporation by all the other members of the Board, and said that he could cordially endorse what had been already said by Mr. Wallace that he believed there was a great future for the Corporation.

Votes of thanks were afterwards accorded to and acknowledged by the chief officers of the staff and the proceedings terminated.

Kensington and Knightsbridge Electric Lighting Company (Limited).

The general meeting of this Company was held at No. 1, Great George-street, Westminster, on the 16th inst., Mr. Granville R. Ryder in the chair, "to receive report of the Directors, to declare dividend to elect retiring Directors and to transact other business of the Company."

The SECRETARY (Mr. R. S. Erskine) read the notice convening the meeting and the minutes of the last meeting, which were approved by the present meeting, and signed by the Chairman as correct.

The CHAIRMAN then said: I beg to move the first resolution:—

"*That the report and accounts now read be adopted, and be entered on the minutes.*"

Before putting that to the meeting, I desire to make a few remarks on the report and accounts now submitted to you. I believe, gentlemen, you will agree with me in thinking that they show substantial and steady progress, though, perhaps, not quite as rapid as we could wish. At the same time there are some features about them which are of an encouraging and satisfactory character. In the first place, with respect to the houses and shops taking the light, the number on December 31, 1891, was 436, while on December 31, 1892, it was 550, an increase of 114; and the 8-c.p. lamps sprang from 38,408 on December 31, 1891, to 47,441 on December 31 last. There is also a very satisfactory increase in the output of units, which jumped from 385,051 in the year 1891 to 535,343 in 1892, an increase of 150,292. The gross earnings per 8-c.p. lamp remained practically about stationary—in fact, rather less than more, being 7s. 7d. per lamp in 1892, as against 7s. 8d. per lamp in 1891. As to the gross earnings, in 1891 they were £12,266, but they have increased in 1892 to £16,628, being an advance of £4,361. The net profits have increased by the sum of £2,446—that is to say, from £4,381 in 1891, to £6,828 in 1892. There is a satisfactory point in these figures, namely, that the ratio of profit to gross earnings has considerably increased. It has increased from 36 per cent. in 1891 to 42 per cent. in 1892. That point might be further elaborated by this fact also—that the increase of profit of £2,446 may be put against the increase of £4,361 in the gross earnings; and in that case the increase would stand at something over 56 per cent. of profits as against gross earnings. That, I think, is an extremely satisfactory item, because it shows that the ratio of profits increases with the increase of business. The next point I would call attention to is as to the capital expenditure for the past year. The total amount spent was £12,800 in round figures, and I may mention the main items on which that outlay has taken place. On buildings £868. 18s. 8d. has been spent. That expenditure has really been on coal bunkers at the Knightsbridge station, and it will tend very much to the economical working of our business in the future. The sum of £1,788 has been spent on batteries, £733 on connecting to mains; meters £1,013, plant £3,764, and mains—this being the largest item—£4,441. No doubt the shareholders will observe that there is a considerable increase in the capital account, and First Mortgage Debentures, issued during the past year—or rather up to December 31 last—amounted to £29,400, whereas in the former account, that is to say, to December 31, 1891, the amount was only £7,930. There would naturally appear to be on the face of it a discrepancy, because £12,800 only has been expended on capital, and the increase in the issue of mortgage debentures has been £21,470. However, by looking at the figures of this year, and comparing them with those of last year, you will see that the item following that of mortgage debentures, "sundry creditors and open accounts," stood at £11,347 in 1891, whereas in the accounts now presented the item is only £3,011. 14s. 4d. That accounts for the difference of £8,000. There is another item on the other side which requires explanation, "suspense account (law)," £1,800. That comes from the action that was brought against us by Mr. Lane Fox As you are aware, we had not to stand the whole expense of that contest ourselves. Some of the other companies, and also some private firms, joined with us. The total cost of the action was over £6,000, and the amount which falls to us is about £2,000. As you are aware, we gained the victory over Mr. Lane Fox, but it is probably true in law, as in many other things, that the next worse thing to defeat is the reverse. Mr. Lane Fox was condemned in costs, but up to the present time they have not been paid, and whether they will be paid or not I cannot say. Negotiations are going on, which we hope may result in his paying our costs. The actual amount of our share he will have to pay will be about £1,300, and this will reduce the amount we have to pay to £300. We only hope that that may be the result, but it is impossible at the present moment to say whether we shall get that £1,300 paid by Mr. Lane Fox. The next item I would call attention to is the first item on the debit side of the revenue account—"To manufacturing electricity, coal, oil, water, waste, wages, and sundries"—amounting to £3,746. 11s. 4d., as compared with £4,067. 11s. 11d. last year. Thus you will see that with an increase of output of very nearly one-third, we have managed that the expense of the production of the electricity should be something like £300 less than that in the year before. That, I think, is a very satisfactory statement, and it reflects the greatest credit upon the staff. The principal item of diminution is in the wages. The coal, which is a very large item, cost very much the same, but the reduction made shows that by devoting their attention to the economical working of our business they have been successful. You cannot have a better proof of that than the fact of their having worked a much larger business at a less cost of £300. The next item which I would draw your attention to is less satisfactory—bad debts. I suppose it is always open to us to have some bad debts, but I hope that the amount will not always be as large as £393. This arises from Hyde Park Court, one of Hobbs and Co's properties. Two quarters had been paid, but in the summer quarter they disputed the amount, and the meters had to be tested. That gave them time, and the result was that when the meters were tested and were

Hosted by Google

found quite satisfactory, they had nothing to pay with. I am afraid we must regard this as lost. With regard to the item of "Renewal account in respect of buildings, mains, plant, and batteries," £3,395. 15s. 7d. That sum includes the actual maintenance, which amounted to £2,124. 15s. 7d., and added to that the £921 which has been written off what you may call antiquated plant, and the sum of £350, by which we have increased the renewal account, increasing it from £1,713 to £2,063. I think these are the only points to which I need call your attention on the accounts, but I shall be very glad to answer any question. There are one or two other things that I would draw your attention to, and one is with respect to the district belonging to the Kensington Parish, which the Chelsea Company have agreed to sell to us. We have had the Wharncliffe meetings with respect to this matter, and it has been approved by the shareholders. The Chairman then indicated on the map the district proposed to be transferred to the Company, and continuing, said : You will see that it comprises by no means a bad district. At the present time it is producing £1,700 a year gross, and I shall be very surprised if, out of that £1,700, we are not able to get 10 or 12 per cent. upon the amount of our purchase money, which is agreed at £7,000. There are 673 houses in this district, and at the present moment only 50 or 60 take the supply, but our mains run the whole way on this side of the new district, and it will be easy to make connections anywhere. The system of the Chelsea Company, too, is the same as our own. We certainly think that this will turn ut a satisfactory bit of business for the Company. There is one other point I would mention before I sit down, namely, with respect to the statement made in the report, that "No provision has been made in the accounts for directors' remuneration." The same remark might have been made with respect to all the accounts that have preceded the present statement; but I should, at the same time, inform you that up to the end of December, 1891, the Directors have been paid by certain shares which were handed over to them by the old Kensington Court Company. The fact is that the Kensington Court Company received from this Company the sum of £25,000, of which £5,000 was not distributed, the idea being that it might be required for paying the expense of syndicating the capital of the new Company. As it so happened, when we tried to syndicate it we were unable to do so, as electric lighting companies were not at the time in favour. We, however, went among our friends, and in that way got the capital without appealing to the public. A good many of the shares were not issued, and about 3,000 were left. The Directors having had no remuneration whatever for six year's work, suggested to the Kensington Court shareholders that they could not lay out this money better than in remunerating the Directors and officers for their work for six years. This was done, and every single shareholder agreed to it. I think it is right, as it might occur to some shareholder to move that some provision should be made for the Directors for their work last year, that they should know the position. The fund is now exhausted, and we must depend at future meetings on what the shareholders may vote to us. I now conclude by proposing the resolution.

Mr. G. H. HOPKINSON seconded the motion.

Mr. SAUNDERS, Q.C., said he desired to congratulate the Directors on the working of the Company. He had made certain enquiries privately, which would avoid the necessity of his asking them at the meeting.

Mr. KILLINGWORTH HEDGES said he also desired to congratulate the Directors on the past year's working, especially on the reduced cost of manufacturing the electricity. At the same time he was rather dis appointed, for the Company had been going on for six years, and they had come to a dividend of only four per cent. on the ordinary shares. He was a shareholder in another company which only started last year—the Electricity Supply Corporation—which, with only 29,000 lights, had got a revenue of £19,717 net ; whereas this Company, with 47,400 lights, had only about £16,000. He did not wish to bring this forward in any invidious spirit.

The CHAIRMAN : That is the Strand Company, is it not ?

Mr. HEDGES, continuing, stated that that was so, and that it used to be known as Gatti's Company. This company's district was, he said, not one in which money could be made as in the case of the Electricity Supply Company and the Pall Mall and St. James' Company, and he desired to point this out as there was a desire to increase their area. He thought that they ought to see if they could not get some richer district. He thought that theirs was too much of a residential district, and as Mr. Crompton once remarked concerning another company, they would do much better if they could supply a few public houses. He could not agree that the Directors were entitled to any more remuneration at present, looking at the trifling dividend of 4 per cent. He did not think that the shareholders should be asked to give any more for Directors' remuneration until a dividend of 5 per cent. was paid. He was not a preference, but an ordinary shareholder. He had had no dividend for some time, then he received 2 per cent., and now he got 4 per cent. He did not think there was much "catch" in his investment, especially as he had joined another company which, in the first year of its working, paid 5 per cent.

The CHAIRMAN : That company has been in existence five or six years, or longer.

Mr. HEDGES, resuming, said that if the Company could get a little more business they would have some more revenue, and there would then be more reason for a liberal payment to the staff. He thought that they had now a "lean year" to face, as he saw that the different companies were reducing their charge per Board of Trade unit, and he presumed that their Company would have to do the same. Moreover, next year they would have rather the dreadful question of how much they would have to pay for the license for the three-wire system. He did not think that this was a year to ask for extra remuneration for the Directors.

Mr. HOPKINSON : We do not ask for extra remuneration, but for some remuneration.

Mr. WYLLIE said he thought that the Directors had done very well indeed, and he proposed that the sum of £350 should be awarded them for their services for last year.

Mr. SAUNDERS, Q.C., in seconding the motion, said he did not at all agree with the idea of allowing directors to work for nothing. He knew many cases of companies which paid no dividend, but the directors of which received handsome fees. He thought that the Directors deserved to be encouraged by the shareholders, and he considered that the sum of £350 was very moderate indeed.

Mr. HEDGES said he thought it would be best to consult the shareholders generally on the matter, nothing having been said in the Directors Report that the subject would come forward.

The CHAIRMAN replied that he did not think the shareholders could be consulted any further than they had been. If they did not come to the meeting it was not the Directors' fault. He then put the motion for the adoption of the report, which was carried unanimously.

Mr. WYLLIE then put the resolution, voting the Directors the sum mentioned, and it was carried.

On the motion of the CHAIRMAN, seconded by Mr. HOPKINSON, the dividend recommended was afterwards declared.

The CHAIRMAN, in answer to a shareholder, said that there was no question as to the right of the Company to get the sum mentioned from Mr. Lane Fox, as judgment had been given against that gentleman in the action which he brought against the Company.

Mr. R. W. WALLACE proposed the re-election of Mr. Hopkinson to his seat at the Board, and said he thought that in doing so he might thank the shareholders for having voted the Directors £350 for their services during the past year. It might be supposed in such a company as theirs, which was not a very large one, there was not so much to do, but he thought that if the shareholders—and especially Mr. Hedges—were to attend one of their board meetings, and saw the amount of work which had to be done, they would think that the Directors were not at all adequately remunerated, although, in the present financial position of the Company, they would not think of asking for more. An enormous amount of work had been done during the past year in connection with matters which had affected what they might, perhaps, call their somewhat infant industry, and these matters had occupied not only their board meetings, but also their very anxious thought and care at other times. Mr. Hopkinson reminded him that there were committees of all the London Electrical Companies which met very frequently, and there was always one member of their Board present at these meetings, for which service nothing was paid. The directors of other Electrical Companies were paid very much more than the Board of this Company. With respect to the extension of the district, the Directors had gone in the matter very carefully, and were certain that it would lead to a very great development in the amount of energy they supplied, while it would pay them at least 10 per cent. on the outlay, and very possibly more—that was, if they only took the present consumers of electricity. With regard to the reduction of price, they were not situated like other companies who had made the reduction. They had no competition in their district. They did, however, make a very considerable reduction to large consumers, and it would be a question that would require very serious attention on the part of the Directors as to whether or not they should make a reduction. The ordinary law of supply and demand, however, did not apply to the reduction of the price of electrical current ; there were other circumstances that influenced this matter. They had not found it desirable at present to reduce their price, but they would do so if they saw that it would lead to an increased amount of business and be advantageous to the shareholders.

Mr. ALFRED S. BOLTON seconded the motion, which was carried unanimously.

Mr. HOPKINSON returned thanks, and afterwards proposed the re-election of Mr. Ryder. He did not think that the Chairman had explained exactly how the shares which the Directors received for their remuneration up to the end of 1891 were divided. The fact was that several of the officers outside the Board had had a considerable amount. As far as he (the speaker) was concerned, he received ten shares, or £50, representing something like two years' work, so that it could not be said that he had been extravagantly paid out of the funds in question. He thought that Mr. Hedges ought rather to blame himself than the Directors for having displayed a want of judgment in investing in the Company if he were not satisfied with the return that he received from it. He did not think that the Directors could be held responsible because the business of the Company had not developed to the same extent as that of other companies supplying more favourable districts. He did not, however, think that there was any reason to complain with regard to the progress of their Company. When he first joined it the total number of lamps were, he thought, 12,000, and now the number was very nearly 50,000. This was in something like four years. Almost every item quoted by the Chairman, and his remarks on the report, showed an improvement of from 25 per cent. to 33 per cent., and he (the speaker) did not think that that was unsatisfactory progress. He only made these remarks because he did not think that any body of shareholders could possibly expect any gentlemen to devote a considerable amount of their time to looking after the interests of the Company for a series of years for nothing. The present, he believed, was the third half-year in which the shareholders had been paid 4 per cent., and he therefore thought that the claims of the Directors for some remuneration might very properly be brought before them.

Mr. HEDGES, in seconding the motion, said that he had not meant in his remarks to make any censure on the Directors. If, however, electricity was "going to go" and to be one of the great commercial enterprises which they hoped it would be, they must pay more than 4 per cent. The public might invest in gas companies to pay them something like 6 per cent., and whereas the latter would be able to on go for ever—

Hosted by Google

except for the action of some very Radical Government—the electric lighting companies had only a certain period to work in, during which they must build up a large reserve.

The motion was carried unanimously.

The CHAIRMAN, in returning thanks, expressed a hope that next year the dividend declared might be better.

The Auditors, Messrs. Lovelock, H. W. Whiffin and Dickinson, were afterwards re-elected, and the proceedings then terminated.

Electricity Supply Corporation (Limited).

The annual ordinary general meeting for 1893 of shareholders of the Electricity Supply Corporation (Limited) was held at the Town Hall, St. Martin's-in-the-Fields, Charing Cross, on Friday, February 17th, in the afternoon, for the following purposes, viz.: (*a*) To receive and consider the annual statement of accounts, balance sheet, and report of the Directors thereon. (*b*) To sanction the declaration of a dividend, and to transact the ordinary business of the Company. (*c*) To elect two Directors in place of those retiring by rotation. (*d*) To elect auditors for the ensuing year and settle their remuneration. Mr. Spencer Chadwick, the Chairman of the Company, presided.

Mr. EDWD. WILMOT SEALE (the Secretary) read the notice calling the meeting, and the report of the Directors was taken as read.

The CHAIRMAN: Gentlemen, In asking you to consider question *a*, that is, to receive and consider the annual statement of accounts, balance-sheet, and report of the Directors thereon, I will ask you to accept that report and the accounts as read. And there are one or two observations that I would like to make in supplementing what is contained in that report; and, first of all, with regard to the reserve fund of £250 that is provided for bad and doubtful debts, and it is, we believe, amply sufficient for that purpose. Then, gentlemen, as to the amount available for dividend, it is, you will see if you will turn to the accounts, £4,248. 19s. 11d., but this amount would have been £5,726. 12s. 9d. but for the fact that we have had to pay out of the profits of the year 1892, in accordance with the directions of the Board of Trade, the debit balances brought forward from last year; that is to say, from the account of 1891, and those debit balances amounted to £919. 14s. 10d. and £557. 18s. 8d. Had it not been for those debit balances that have had to be paid out of the profits, the dividend for this year would have been two and a-half per cent. more than it is. The profits for the last half-year of 1892 show a large increase of business, and, I think that if anything like the same amount of progress is maintained in 1893, the result of that year will to a very great extent be in excess of the result for 1892. Negotiations are now pending with likely customers which will probably result at an early date in a large increase in our supply of current to the extent we expect, of 4,000 to 5,000 more lamps of 8-candle power each. That will be a large increase, but it will be maintained, this extra number of lamps of 4,000 or 5,000, without our having to make any increase in the plant and without incurring any outlay in any way for any extra machinery. Indeed, our present plant is sufficient—more than sufficient—to supply that number of extra lamps. Then as to the working capital, you will have seen that there is not a very large sum in the accounts in respect to working capital, but as there is an available balance at the bankers in cash, the Directors consider that, inasmuch as they have the call upon £19,100, it is in the interest of the shareholders not to call up one shilling more for working capital than is absolutely required from time to time. By adopting this course they will save a very considerable amount in interest upon capital that would have to be paid if the money were called up either in the shape of dividend on shares or interest on debentures. The Directors propose to set aside a substantial sum during the present year on account of depreciation which they have not felt themselves justified in doing during the past year, which these accounts cover inasmuch as the whole of the machinery and plant is still equal to new. Everything has been maintained in a state of thorough efficiency, the Secretary will read to you the engineer's report in regard to this if you wish it. The balance carried forward after paying the dividend (assuming you declare a dividend of 5 per cent. to-day) will be £375, and that of course will be available for dividend next year. Gentlemen, with these remarks I propose,

"*That the report and accounts be adopted and that the dividend as recommended at the rate of 5 per cent. per annum be declared.*"

Mr. G. H. BROUGHAM GLASIER: Gentlemen, our Chairman has placed before us very clearly the position of the Company, and what with his statement and the printed accounts there is really no need for further explanation, and I will content myself with merely seconding the resolution,

"*That the report and accounts be received and adopted and that the dividend at the rate of 5 per cent. per annum be declared.*"

The CHAIRMAN invited discussion.

Col. YOUNG: I would like to ask a question. It is simply to ask for a little information of an item which appears in account No. 7, viz., sundry debtors, £7,302. I would like to know why so large an amount stands in the accounts, and whether it has been reduced since the accounts were made up. I have no doubt that there is an easy explanation for it. Then there is another question that I would like to ask—I do not know whether our shares are yet quoted on the Stock Exchange. I would like to know if any steps have yet been taken to fulfil the promise of the prospectus, that application would be made in due course to the Stock Exchange for a quotation. I wish to know whether such application has been made, and if so, what was the result of it; and if it has not been made, why it has not been made?

The CHAIRMAN: With regard to the £7,302 sundry creditors, there could not be otherwise than a large amount owing at December 31. Having regard to the large amount of current supplied, you will observe on the other side of the account that there is the item of sundry creditors, and, of course, the one is set against the other. The quarter that these accounts refered to is the Christmas quarter, which is a heavy one, and as you know these accounts were not made up to to-day or yesterday, but to the 31st December, and the quarter only closed on the 25th December, and it would be impossible to collect the accounts for some days or even some weeks.

Col. YOUNG: What proportion does that £7,000 bear to the total?

The CHAIRMAN: It is about one-third that has been received.

The SOLICITOR: If you look to the accounts you will see that the sales of current during the year were £19,717, and the £7,000 was outstanding on December 31.

Col. YOUNG: I am glad to hear so satisfactory a reply.

The CHAIRMAN: The Christmas quarter is a very heavy one.

Col. YOUNG: I am satisfied.

The SOLICITOR: As to the Stock Exchange quotation: as you know, the whole of the capital of the company has not yet been taken up, and therefore it would be impossible under the rules of the Stock Exchange to obtain a quotation in the present state of things, and therefore it is impossible at present to entertain any application. It is not worth while making the application until we are likely to meet with a fair prospect of success.

Mr. MILLER: I suppose a large proportion of that £7,000 has since been paid?

The CHAIRMAN: Yes, the bulk of it.

The resolution was carried unanimously.

Mr. LING then moved the re-election of the retiring Directors, Messrs. George Henry Brougham Glasier and Isaac Percy Mendoza.

Mr. PEDLER seconded.

The motion was carried.

Mr. CHAPPLE moved the re-election of the retiring Auditors, Messrs. O. R. Johnston and Son at a remuneration of £50.

Col. YOUNG seconded the motion.

The resolution was carried.

The CHAIRMAN: That concludes the business of the meeting. I am much obliged to you for your attendance, and you will receive in due course your cheques for the dividend.

Mr. WYBROW ROBERTSON moved a vote of thanks to the Chairman.

Mr. CHAPPLE seconded the motion.

The resolution having been carried, the Chairman briefly returned thanks, and the meeting then separated.

Telegraph Construction and Maintenance Company (Limited).

The following report of the Directors of this Company will be submitted to the members at the twenty-ninth ordinary meeting to be held on Tuesday next, the 28th inst., at the offices of the Company, 38, Old Broad-street, E.C., at one o'clock:—

The accounts for the year show a net profit of £51,579. 1s. 5d., after charging the interest on the debentures. To this sum must be added £57,084. 0s. 4d. brought forward from last year, making a total of £108,663. 1s. 9d. From this amount is deducted the interim dividend of 5 per cent., paid July 12, 1892, amounting to £22,410, leaving £86,253. 1s. 9d. to be dealt with. Of this sum the Directors propose to distribute a dividend of £1. 4s. per share, absorbing £44,820, being at the rate of 10 per cent., and making, with the amount already paid, a total dividend for the year of £1. 16s. per share, or 15 per cent., free of income-tax, leaving £41,443. 1s. 9d. to be carried forward to the next account.

During the past year the following works have been carried out, viz.:—A cable has been manufactured, and laid between Santos and Chuy, on the coast of Brazil, for the Western and Brazilian Telegraph Company. A cable has been manufactured, and laid on the coast of Sumatra, for the Eastern Extension Telegraph Company, on account of the Dutch Government. Repairs have been made for the German Government in their Valentia-Greetseil Cable; for the Direct United States Telegraph Company in their cable off the Coast of Nova Scotia; for the Western and Brazilian Telegraph Company in their lines off the coast of Uruguay; and in the Anglo-American Telegraph Company's Brest-St. Pierre Atlantic Cable. A contract has also been made with the African Direct Telegraph Company for connecting Bonny, on the West Coast of Africa, with the Cameroons River, on account of the German Government; and an agreement has been entered into with the West Coast of America Telegraph Company for the supply of a cable to connect Valparaiso and Talcahuano, the greater portion of these two lengths having been manufactured in 1892. Various lengths of cable have been manufactured for different telegraph companies during the year, and a total length of 4,222 miles of wire insulated for submarine and land lines.

The Company's steamships, and their factories at East Greenwich and Wharf-road, are in efficient condition.

The Directors regret that their colleague, Admiral of the Fleet Lord John Hay, has resigned his seat on the Board, owing to the impossibility of his giving adequate attention to the Company's affairs through his being obliged to pass the winters abroad. In accordance with the Articles of Association, the Directors have appointed Sir Robert G. W. Herbert, G.C.B., to fill the vacancy thus occasioned.

The retiring Directors are Mr. James Pender and Sir Robert G. W. Herbert, who, being eligible, offer themselves for re-election. The meeting will have to appoint auditors for the ensuing year. Mr. John Gane (of the firm of Messrs. Gane, Jackson and Jefferys) and Mr. Patrick A. Glegg (of the firm of Messrs. Welton, Jones and Co.), who retire, offer themselves for re-election.

Hosted by Google

Chelsea Electricity Supply Company (Limited).

The following is the Directors' report, to be presented at the annual meeting to be held at the Central Station, Draycott-place, S.W., on Thursday, the 2nd prox., at 11 a.m. :—

The net profits for the year ended December 31, 1892, after paying debenture interest, amount to £1,336. 2s. 7d., out of which it is proposed to pay a dividend on the Ordinary shares at the rate of 2½ per cent. per annum, carrying forward the sum of £176. 10s. 1d. to next year. In considering these results it must be remembered that a large proportion of the Company's capital is in the form of debentures. To meet the necessary increase in capital expenditure, the balance of the First Mortgage Debentures and £3,700 of the Second Debentures were issued during the year as the money was required for new works. Important additions have been made to the plant and various improvements have been effected. The whole of the plant, including the accumulators, is in thorough working order. A very gratifying feature of the accounts is the large saving shown in the consumption of coal. There were 357,162 units of electricity sold during last year, the expenditure on coal being £2,433, as against £2,692 in 1891, when 290,458 units were sold. The total cost of each unit of electricity sold was 5½d. in 1892, against 7d. in 1891. The number of lamps on the Company's mains at the end of 1892 was 34,876, being an increase of 27 per cent. for the year. The Directors have every confidence that the accounts for the current year will show still further improvement.

The transfer of the Company's area in South Kensington was, subject to the confirmation of Parliament, approved at the extraordinary general meeting held on the 14th inst. The Directors are of opinion that this transfer will be of advantage to both Companies.

In May last Mr. Frank King was appointed managing engineer of the Company, and the appointment has already produced very satisfactory results.

The retiring Directors are Sir George Prescott, Bart., and Mr. E. Garcke, who, being eligible, offer themselves for re-election. The auditors, Messrs. Cooper Brothers and Co., also offer themselves for re-election.

Notice is also given that an extraordinary general meeting will follow, when the subjoined resolution, passed at the extraordinary general meeting held on February 14th last, will be submitted for confirmation as a special resolution :—

"That the Bill proposed to be introduced in Parliament in the ensuing Session, and now laid before this meeting, intituled 'A Bill for confirming an agreement for the transfer to the Kensington and Knightsbridge Electric Lighting Company (Limited) of the undertaking of the Chelsea Electricity Supply Company (Limited), authorised by the South Kensington Electric Lighting Order, 1889,' be, and the same is hereby approved, subject to all such additions, alterations, and variations as Parliament may think fit to make therein."

NEW COMPANIES, STATUTORY RETURNS, &c.

[*In addition to the information given under this heading, detailed particulars of many of the Companies whose returns appear below will be found in* "THE ELECTRICIAN" ELECTRICAL TRADES' DIRECTORY AND HANDBOOK, 1893, pages 320-348, *&c., &c.*]

CREDENDA TUBE COMPANY (LIMITED).—This Company was registered on the 14th inst. with a capital of £100,000, in £10 shares, to acquire and take over as a going concern the business of tube makers, hitherto carried on by the Credenda Seamless Steel Tube Company (Limited).

CROWN CONTRACT AND WORKS COMPANY (LIMITED).—This Company was registered on the 16th inst. with a capital of £10,000, in £1 shares, to construct, execute, repair and maintain in any part of the world railways, tramways, docks, water and gas works, telegraphs, telephones, electric works, or works for the supply or use and application of electricity for lighting, heating, or motive purposes, and any other public or private works.

JAMES MACINTYRE AND CO. (LIMITED).—This Company was registered on the 16th inst., with a capital of £50,000, in £10 shares, to carry on the business of earthenware and china manufacturers, and manufacturers of apparatus and appliances for electric work and otherwise, at the Washington Works and Victoria Mill at Burslem, Staffs.

TUCKINGMILL FOUNDRY AND ROCK DRILL COMPANY (LIMITED).—This Company was registered on February 14, 1893, with a capital of £50,000, in £5 shares, to carry on the business of iron and brass founders, mechanical and electrical engineers, &c., at Tuckingmill, Cornwall,

WILLIAM HOUGHTON AND CO. (LIMITED).—This Company was registered on the 16th inst., with a capital of £10,000, in £10 shares, to carry on the business of electrical and general engineers, machinists, iron and brass founders, &c.. at Great Grimsby.

SWINBURNE AND CO. (LIMITED).—This Company was registered on the 16th inst., with a capital of £25,000, divided into 300 deferred shares of £5 each (Nos. 1 to 300), and 4,700 ordinary shares of £5 each (Nos. 301 to 5,000). The objects are: To carry on the business of electrical engineers, electricians, engineers and contractors, suppliers of electricity, manufacturers of electrical apparatus, and mechanical and chemical engineers, and also the business of producing light, heat, sound, and power by means of electricity, magnetism, galvanism, or otherwise, and to carry on any other business which may be considered able to be conveniently carried on in connection with the business of the Company, or which may be conducive to the interests and progress of the Company. The subscribers are :—

	Shares.
James Swinburne, 49, Queen's-road, Wimbledon, London, S.W., electrical engineer	1
Bertram R. Beale, Angel-lane, Northampton, electrical engineer	1
Harold E. S. Holt, Oaklands, Teddington, electrical engineer	1
Joseph Holt, The Grange, Farnborough, Hants	1
Captain Francis G. R. Slaney, Glandore Bassett, Southampton	1
Edith M. S. Kenyon-Slaney, Glandore, Bassett, Southampton	1
Hewitt Bostock, The Hermitage, Walton Heath, Epsom	1

The first Directors of the Company are:—James Swinburne, Harold E. S. Holt, Bertram R. Beale, Wroth Lethbridge, and Hewitt Bostock, the first three of whom are the first managing Directors.

EMILE LANSARD SYNDICATE (LIMITED).—At a meeting held at 216, Goswell-road, E.C., on the 13th inst., it was resolved to voluntarily wind up the Syndicate, and Mr. J. Boss, of 9, Fleet-street, E.C., was appointed liquidator.

FOWLER, LANCASTER, AND COMPANY (LIMITED).—The annual return of this Company, made up to December 8, 1892, has been filed. At the time of making up 1,782 shares, out of a nominal capital of £22,000, in £10 shares, were taken up, of which 620 were issued as fully paid. Upon the remaining 1,162 shares the full amounts were called, and all calls (£11,620) paid.

FROUDE-HURRELL TORPEDO COMPANY, LIMITED (in Liquidation).—Proofs of debts must be sent in to Mr. C. J. Stewart, the official receiver and liquidator, 33, Carey-street, W.C., by March 4th.

ISLINGTON AND GENERAL ELECTRIC SUPPLY (LIMITED).—The annual return of this Company, made up to January 12, 1893, has been filed. The Company was registered on June 28, 1890, with a capital of £1,000, in £1 shares, as the "Camberwell and Islington Electric Light and Power Supply (Limited)," and formed one of a large number of companies promoted and registered with a view to the acquisition of electric lighting orders in the districts referred to in their titles. The capital was subsequently increased to £250,000, in £5 shares, by the creation of 49,820 new shares, and a public issue attempted. This was unsuccessful, as, at the time of making up, only 27 shares were taken, resulting in a payment of £107.

MOUNTAIN'S WIRE MANUFACTURING COMPANY (LIMITED).—A petition for the compulsory winding up of this Company was presented on the 15th inst. by Messrs. Leatham, Tew, and Co., bankers, of Pontefract, and is down for hearing at the Royal Courts of Justice on March 11.

ST. JAMES' AND PALL MALL ELECTRIC LIGHT COMPANY (LIMITED).—The annual return of this Company, made up to February 8th, was filed on the 15th. The nominal capital is £200,000, divided into 100 founders shares of £1 each, 19,980 ordinary shares of £5 each, and 20,000 £7 per cent. preference shares of £5 each. All the shares have been taken up, the full amount called, and all calls paid.

CITY NOTES, &c.

CITY AND SOUTH LONDON RAILWAY COMPANY (LIMITED).—The traffic receipts for the week ended February 19th were £938, as against £872 for the corresponding period of last year, being an increase of £66. The total receipts for half-year amount to £6,800, against £5,905 in the corresponding period of 1892, being an increase of £895.

EDISON AND SWAN UNITED ELECTRIC LIGHT COMPANY (LIMITED).—The Directors of this Company notify that a payment on account of the dividend of the current year will be made at the rate of 3½ per cent. for the half-year on the "A" shares, with the addition of a payment at the rate of 4·68 per cent. for the half-year in respect of accumulated arrears. This will work out in the following manner :—On the 89,261 shares, £3 paid, 3s. 7¾d. per share ; on the 5,000 fully-paid shares allotted to the Edison Company, 6s. 0⅝d. per share ; on the 12,139 fully-paid shares allotted to the Swan United Company, 4s. 7¾d. per share. The payment will be made upon the register of February 21st inst., and the dividend warrants will be issued on March 14th next.

LONDON PLATINO BRAZILIAN TELEGRAPH COMPANY (LIMITED).—This Company give notice that the half-yearly coupons falling due on the 1st prox. of the £100,000 Six per Cent. Debentures will be paid by Messrs. Glyn, Mills, Currie, and Co., 67, Lombard-street, E.C., on and after that date. Coupons should be left with the bankers for three clear days.

STOCK EXCHANGE NOTICES.—The Stock Exchange Committee appointed yesterday (Thursday) a special settling day in the vendors' ordinary shares, Nos. 31,437 to 40,000, of Woodhouse and Rawson United (Limited).

TELEGRAPH CONSTRUCTION AND MAINTENANCE COMPANY (LIMITED).—The transfer books of this Company will be closed up to the evening of the 28th instant preparatory to the payment of dividend to all shareholders whose names were on the register on the 20th instant.

WEST AFRICAN TELEGRAPH COMPANY (LIMITED).—This Company announce that the half-yearly interest due on March 1st next on the Five per Cent. Mortgage Debentures will be paid on and after that day by the National Bank of Scotland, 37, Nicholas-lane, E.C. Coupons should be left with the bankers three days for examination.

Hosted by Google

WESTERN AND BRAZILIAN TELEGRAPH COMPANY (LIMITED).—The traffic receipts for the week ended February 17, 1893, after deducting 17 per cent. of the gross receipts payable to the London Platino-Brazilian Telegraph Company (Limited), were £3,233.

WEST INDIA AND PANAMA TELEGRAPH COMPANY (LIMITED).—The receipts for the two weeks ended February 15th were £3,011, as compared with £2,635 for the corresponding period of last year. October, estimated at £4,121, realised £4,111.

AT LESS THAN HALF-PRICE.

WESTINGHOUSE TYPE.

IN consequence of the recent decision respecting Incandescent Lamps in the U.S. Courts, thousands of Lampholders have suddenly been thrown upon the Market by several Manufacturers and Supply Houses, the bulk of which have been purchased by our New York House at an enormous sacrifice, which enables us to sell them at less than half-price.

Lot 1.—KEY AND SWITCH SOCKET HOLDERS.

3,400 Edison Screw Caps.*	4,900 Westinghouse Modern Type.
1,200 Thomson-Houston.	5,800 Sawyer-Man System.

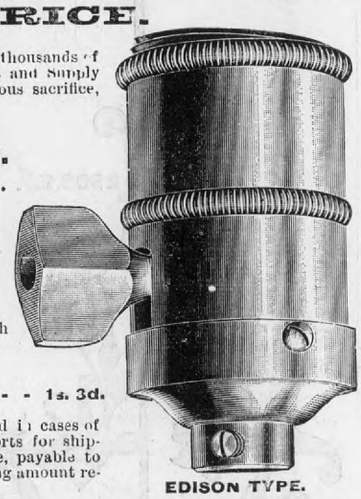
Lot 2.—PLAIN POLISHED BRASS LAMPHOLDERS.

6,600 Sawyer-Man Improved.	5,000 Westinghouse Type.
1,800 Thomson-Houston System	4,000 Edison Acorn.*

Marked * not for use in England. All other types fitted to Loop Lamps, with Cord Grips complete, 3d. extra.

SALE PRICE FOR ALL SYSTEMS:—

Key and Switch Sockets - 1s. 9d. | Plain Polished Brass - - - 1s. 3d.



EDISON TYPE.

For the convenience of Electrical Engineers and Shippers, these goods are packed in cases of 50, 100, and 200 lots (free of charge), delivered f.o.b. Rotterdam or New York Ports for shipment to any part of the World. All Orders executed in rotation on receipt of cheque, payable to HENRY F. SHIPPEY and CO., crossed Brown, Shipley and Co., Bankers, London, covering amount required. **10 per cent.** extra discount on lots of 1,000. Further particulars from—

WHOLESALE AND EXPORT ONLY.

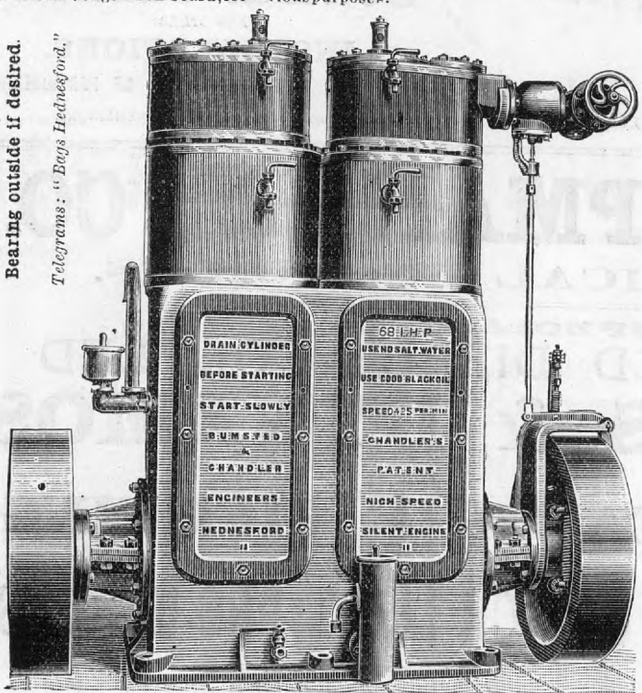
"SILENT" ENGINES (CHANDLER'S PATENTS)

FOR ELECTRIC LIGHTING.

Made in **20** SIZES, with one or two cranks, from 2 to 200 Horse-power, **simple compound or tri-compound, giving the highest economy,** at speeds suitable for coupling direct to dynamos for THEATRE-LIGHTING, for CENTRAL STATIONS, for SHIP-LIGHTING, and TRAIN-LIGHTING.

Electrical Firms and Shipowners may place perfect confidence in these Engines, as they are the most durable ever introduced, and as economical as any other high-class engine. After prolonged and severe tests (which caused the engines of other makers to break down) these engines were selected for use on ss. "*Teutonic*": these worked so satisfactorily that they were also selected for ss. "*Majestic.*" Each ship now has 17 engines on board, for various purposes.

Bearing outside if desired. *Telegrams: "Boys Hednesford."*



One Electrical Firm has ordered no less than 40 engines in two years, another firm 32, another firm 19, another firm 16, another firm 14, and a large number of other firms have sent many repeat orders. Twenty of the British India Steam Navigation Company's Steamers are lighted by these Engines. All this goes to prove that the Engines are reliable and highly satisfactory. Many are working without lubrication to Cylinders. NO AIR NOR OIL CAN POSSIBLY PASS AWAY TO CONDENSER.

Every part can be got at comfortably when the door is removed.

Speed adjustable while Engine is running. Requires less care than any other Engine known, and uses less oil. **NO OIL IS LOST.** Engine easily understood. No complications Inside. Constructed to stand hard work. The Patent "Safety" Governors are Extremely Sensitive. They are mounted on the Crank Shaft and require no belt to drive them, and are everlasting.

Letter from Superintending Engineer of Sixteen Steamers with these Engines on board, says:—"*All the Engines are working very satisfactorily.*"

CHANDLER CROMPTON COMBINED COMPOUND PLANT.

For SHIP LIGHTING and TRAIN LIGHTING, as supplied to the Cape Government Railways and many Steamers.

WHEATLEY KIRK, PRICE and GOULTY

(ESTABLISHED 1850).

ELECTRICAL AUCTIONEERS, VALUERS, AND ARBITRATORS.

49, QUEEN VICTORIA STREET, LONDON, E.C.

And Albert Square, MANCHESTER.

SALES BY AUCTION, &c.

WEDNESDAY, MARCH 8TH, 1893.

SALE of ELECTRIC MOTOR TRAM CARS, DYNAMOS, SUBSTANTIAL IRON BUILDING, SHAFTING, FURNITURE, and Other Effects.

WHEATLEY KIRK, PRICE AND GOULTY are instructed to SELL BY PUBLIC AUCTION,

On WEDNESDAY, March 8th, 1893, at the Electric Tram Car Station, known as Plashet Hall Works, Romford-road, Forest Gate, London, E., commencing at 10 for 11 o'Clock prompt,

The ENTIRE CONTENTS of the above Premises.

The Sale will include SUBSTANTIALLY ERECTED TIMBER-FRAMED STRUCTURE, 144ft. long, 35ft. wide, 12ft. high from floor line to eaves, timber roof covered with galvanised corrugated iron, glazed louvres, and two pairs of large folding doors, built specially for removal; SIX ELECTRIC MOTOR CARS, specially built for 4ft. 8½in. gauge, together with a variety of Plant, Furniture, and Effects.

Catalogues may be had from the Auctioneers, WHEATLEY KIRK, PRICE AND GOULTY, 49, Queen Victoria-street, London, E.C.; and Albert-square, Manchester. Telegrams, "Indices, London."

SALE OF HIGH-CLASS MACHINE TOOLS, ENGINES, DYNAMOS, PLUMBERS' and ELECTRICAL FITTINGS.

WHEATLEY KIRK, PRICE AND GOULTY are instructed to include in their Sale at the Electric Tram Car Station, Forest Gate, London, E., as above, about 20 NEW HIGH-CLASS LATHES; also Electroliers, several thousand Switches, Lamp Holders, Instruments, Dynamos, Motors, new Shaping Machine, new High-speed Vertical Engines, about 1,000 dozens Yellow Metal Gas Fittings, consisting of Cocks of various kinds, Sockets, Pendant Bodies, Unions, Swivels, Bracket Backs, Ceiling Plates, &c.; 600 dozens Bib and Stop Cocks, Plumbers' Brass Work and Gun-metal Steam Fittings.

Catalogues may be had from the Auctioneers, WHEATLEY KIRK, PRICE and GOULTY, 49, Queen Victoria-street, London, E.C.; and Albert-square, Manchester. Telegrams, "Indices, London."

MOODIE'S GOLD MINING AND EXPLORATION COMPANY (LIMITED).

TRANSMISSION OF ELECTRICAL POWER.

TO CONTRACTORS.

TENDERS are invited for the SUPPLY and ERECTION, upon the Company's Estate, near Barberton, South African Republic, of certain MACHINERY, PLANT, &c., for the purpose of

GENERATING and TRANSMITTING 250-H.P. by Electricity to various Sub-companies.

Specification and Conditions of Contract, &c., can be obtained from, and Plans seen, at the following places:—

OFFICES OF THE COMPANY:

Pietermaritzburg, Natal;
Moodie's near Barberton, South African Republic;
No. 8, Old Jewry, London, E.C.;

and at

Johannesburg (Messrs. Redwood and Watson), P.O. Box, 500;
Capetown (E. R. Syfret, Esq.), 39, St. George's-street;
America: Messrs. Corner Bros. and Co., New York, in conjunction with their Boston Agents.

Tenders, together with Specification and Conditions of Contract, &c., duly signed, attached thereto, must be sent in to the Head Office of the Company, Pietermaritzburg, Natal, by Noon on the 3rd day of MAY, 1893, and a Duplicate Copy must be lodged with the London Office, 8, Old Jewry, E.C., by the same time.

A Fee of Three Guineas will be charged for Copies of Specification, Conditions of Contract, &c., and inspection of Plans, which will be returned on receipt of a bona fide Tender.

The Lowest or any Tender not necessarily accepted.

By Order of the Board of Directors,
C. J. MACFARLANE, Secretary.
Moodie's Gold Mining and Exploration Co. (Limited).

Pietermaritzburg, Natal,
January, 1893.

BOROUGH OF DEWSBURY.

ELECTRICITY.

The CORPORATION invite TENDERS for the CONSTRUCTION, SUPPLY, and LAYING DOWN of the necessary PLANT and MAINS for the SUPPLY of ELECTRICITY in the Borough, in accordance with the specification, plan, and form of tender, which can be obtained from the undersigned after Friday, the 3rd March, on payment of £2. 2s., which will be returned on receipt of a bona fide tender.

The person or firm whose tender is accepted will be required to enter into a contract and a Bond with two approved sureties for the due performance of the contract. Sealed tenders, endorsed "Electricity," to be delivered at this office not later than THURSDAY, the 23rd March.

Firms tendering may tender for the whole or any part of the Plant.

The Corporation do not bind themselves to accept the lowest or any tender.

By order,
E. MAWDESLEY, Town Clerk.

Town Clerk's Office, Town Hall,
Dewsbury, 2nd March, 1893.

THE ELECTRICIAN:

A WEEKLY ILLUSTRATED JOURNAL OF

ELECTRICAL ENGINEERING, INDUSTRY AND SCIENCE.

No. 772.—Vol. XXX. FRIDAY, MARCH 3, 1893. PRICE FOURPENCE.
Annual Subscription (U. K.), 19/6

NOTES.

The review of Mr. Mottelay's work, entitled "William Gilbert of Colchester, Physician of London, on the Loadstone and Magnetic Bodies," &c., which will be found in another column, discusses everything but the translation. It may be remarked that one of the first resolutions of the Gilbert Club was that their book should contain nothing but a translation, and that the best possible; so that the reviewer deals only with matters entirely outside the scope of the Gilbert Club scheme. The correspondence on "Gilbertiana," though happily dropped in *The Electrician*, has been raging elsewhere, and the first two letters which appeared in our columns have been freely reprinted in American and English journals, but the trenchant rejoinder, which we published on December 30th, has been discreetly ignored. In addition to many unpleasant insinuations the Gilbert Club was warned not to appropriate the valuable footnotes which would be found in the American edition. This, in connection with the resolution to which we have referred, is rather amusing. Indeed, the general merriment of our American friends over the supposed discomforture of the Gilbert Club was without much point, when we remember that the English translation was essentially a subscription one, and that an ample list of subscribers had been obtained long before the advent of its so-called rival.

In connection with the discussion which has lately appeared in our correspondence columns with reference to the priority of the discovery of the alternate-current motor described by Mr. Brown in *The Electrician* for January 27th, we would refer our readers to a brief summary of the work of MM. Hutin and Leblanc published in our present issue. It will be noticed that the motor they allude to has this characteristic in common with Mr. Brown's, viz., that no torque whatever is developed by the motor until the armature is set in motion. In order to overcome this very serious defect the same device is resorted to in each case, since the Tesla method of using two field magnet currents in different phase is adopted for starting the motor. In each case, when the motor is in motion, the torque increases with the speed until synchronism is nearly attained; but whereas Mr. Brown only uses a single wound armature, MM. Hutin and Leblanc employ one which is double wound.

When the field-magnets of a dynamo are excited with an alternating current, the magnetic field produced may be regarded as a revolving field of nearly constant strength, the speed of revolution corresponding with the frequency of the alternating current. If the armature of this machine be rotated at some other speed, the frequency of the alternating current induced in its coils will correspond with the sum or difference of the speeds, according as the armature is rotated in the opposite, or in the same, sense as the inducing magnetic field. It is on an effect of this kind that the action of Hutin and Leblanc's motor depends. Prof. Trouton made use of the same principle when endeavouring to produce currents of high frequency for electric radiation; and our readers will find a description of his experiments in *The Electrician* for January 22, 1892.

In this issue we print a communication sent to us by Signor Riccardo Arno, on rotating electric fields, and it will be noticed that his experiments are exactly analogous with those of Prof. Galileo Ferraris on rotating magnetic fields. The new alternate current motor which is the result of these researches is nothing more than a toy, since its output is less than a thousandth of a horse-power; but the experiments are of much interest from a theoretical point of view. The author maintains that the experiments show that the dielectrics of condensers absorb energy from electrical hysteresis when subjected to an alternating electrical field. But while these researches, and previous ones by Mr. Steinmetz and others, undoubtedly show that energy is absorbed, they cannot be said to prove the existence of true hysteresis. The phenomenon of residual absorption in condensers is in many ways comparable with that of residual magnetism, but there is this great difference between them, that the former depends on time while the latter is independent of it. The waste of energy due to hysteresis in any particular cycle of magnetic changes is the same, however quickly or however slowly the cycle is performed; but no one has yet shown that the loss in the dielectric of a condenser every time it is charged and discharged depends only on the amount of charge.

We cannot at present agree with Signor Arno that the rotation of the armature of his motor is caused by the lag of the polarisation of the cylinder behind the rotation of the electric field causing it. In a Ferraris or Tesla motor such a lag takes place. This, however, is not due to hysteresis, but to the fact that the eddy currents induced in the iron core, or the copper circuits surrounding it, shift the magnetism of the core. Something similar must occur in the dielectric armature of the Arno motor.

Hosted by Google

The result of a very careful determination of the mechanical equivalent of heat, by Messrs. Griffiths and Clark, of Cambridge, has been communicated to the Royal Society. In thermal units Fahrenheit the result was 778·99 foot pounds. The nearest previous determination was that of Rowland. M. Miculescо, in 1891, obtained a result equivalent to 772·3, and Prof. Marks, in 1885, gave 772·8. These latter values agree very well with the 772, or as given in some books, the 772·5 of Joule; but Joule's own results have to be intrepreted by the light of subsequent research. Prof. Rowland has made a careful comparison of Joule's thermometer with the air thermometer, and a further correction was necessary, since Joule had assumed Regnault's expression for the specific heat of water. Mr. Griffiths gives the result of these corrections in his Paper, and finds that after all corrections the value resulting from Joule's own experiments is 776·74. Joule's equivalent must henceforth be known in round numbers as 779.

For many years past the Post Office authorities have been seeking some means of putting an end to the free message system imposed upon them by the railway companies in 1870 as part of their price for assenting to the telegraphs being transferred to the State. The privilege which they enjoyed, and exercised with limitations, under the old telegraph companies has been so much appreciated, or, as some would say, abused, that the number of free railway messages has increased more than fifteen-fold, and, allowing for unrestricted length, probably twenty-fold. At a moderate estimate the Postal Telegraph revenue has been losing between £30,000 and £40,000 a year by this arrangement, and the loss is a steadily growing one. The present Postmaster-General now announces that two of the railway companies have been induced to accept the principle of commutation in extinction of their privilege; and he hopes that the rest of the companies will follow the example. It seems to us that this is one of those cases where Parliament is entitled to impose its own conditions upon any concessions to railway companies asking for increased powers who refuse to come to terms with the Telegraph Department.

In our "Notes" columns this week will be found some statistics relative to the growth of the telegraph system of the Caledonian Railway since 1870. Making all due allowance for natural increase in the length of line open and in train mileage—the average increase of these since 1870 for all the railways of the United Kingdom being respectively about 30 per cent. and 40 per cent.—the comparative figures given are still remarkable. In 1870 the telegraph wire mileage of the Caledonian Railway was only some 3,600, to-day it is over 10,000, an increase of 180 per cent., whilst the number of instruments used to-day is fifteen times greater than twenty-two years ago.

The bulk of this increase may be taken as arising from Board of Trade interference with the management of railways; an interference which, as in the case of the electric lighting industry, has the direct sanction and encouragement of the Legislature, and by the side of which the feats of the Electrical Department look quite puny. Notwithstanding all this, English railways pay, and pay well, having regard to the regularity of their dividends, and are acknowledged by all to be beyond compare the safest in the world. The moral would seem to be, not that interference in one case will bear equally good fruit in another totally dissimilar, but that Board of Trade interference does not of necessity, as some pessimists would have us believe, spell Ruin.

As the day for the opening of the "World's Fair Columbian Exposition" approaches, the weekly "News Letter—No Delay," which is dropped from the "Publicity and Promotion Department," like "the gentle rain from heaven," upon those who do and those who do not want it, becomes more and more "calculated to enthuse." In the latest budget of "pars" we note, amongst other items, that the Queen Regent of Spain will be represented at Chicago by the Infanta Eulalia, the unfortunate Infanta's exact age being duly chronicled; that an English salt concern has taken the liberty of sending a rock-salt model of the Bartholdi statue; and that the King of Siam has decided to make an interesting display. The *pièce de resistance* of this bill of fare, however, is the announcement that the winning exhibitors at the World's Fair will each receive a bronze medal and a handsome diploma, setting forth the specific purpose for which the medal was awarded. "*Provision will be made, it is expected, for 75,000 medals and diplomas.*" We guess this is the biggest provision of the kind ever made.

Manchester.—The Municipal central station is expected to come into operation in June.

Athens.—The central lighting station has now 63 arcs and over 14,000 8 c.p. lamps connected to the mains.

Ealing.—The Ealing Local Board are making application to borrow £30,000 for the purpose of lighting their district by electricity.

Mica.—The Eel Lake, Ont., mica mines have been purchased by the General Electric Company of America, and will be at once put in operation.

Brighton.—On Tuesday next a Board of Trade inquiry will be held concerning the application of the Brighton and Hove Electric Light Company.

Royal Society.—The following Paper was down for reading yesterday:—J. H. Gray and J. B. Henderson: "The Effects of Mechanical Stress on the Electrical Resistance of Metals."

The Hopkinson Three-Wire Patent.—The Westinghouse Company are negotiating with the Dundee and Glasgow Corporations with reference to the three-wire patent.

The Lahmeyer System of Distribution.—A central station on this system has been opened at Bockenheim (Frankfort). Herr Lahmeyer employs four-pole drum armature machines and dynamotor substations.

Aberdeen.—At a meeting of the Plans Committee of the Town Council last week, the plans of the new electric lighting buildings were approved of. The buildings are to be erected near the Gasworks at a cost of £3,500.

The National Telephone Company.—The National Telephone Company has lodged a petition against the addition of certain new clauses proposed to be inserted in the Leeds Corporation (Consolidation and Improvement) Bill.

Hosted by Google

A Telegraph Line from the Pamirs to Pekin. — It is accepted as true in Vienna, says the *Daily News* correspondent there, that the Chinese Government has decided to lay a telegraph line from the Pamirs to Pekin.

The American Proposals with regard to Electrical Units.—The Société Internationale des Electriciens devoted its Wednesday meeting to a discussion of the recent proposals of the American Institute of Electrical Engineers with regard to electrical units.

The Cost of the Electrical Horse-Power Year in Berlin.—As current for power purposes is now supplied from the Berlin mains at the rate of 2½d. per kilowatt-hour, the cost of the electrical horse-power year of 3,000 working hours amounts to £23. 10s.

Dundee.—On Monday evening last the municipal central station came into operation, the current being turned on to several of the establishments which had been wired. It is expected that the public lamps in the High-street will be lit about a fornight hence.

Reduced Rates to China.—The Eastern Extension Company notify that on the 1st inst. the tariffs for telegrams to all places in China, except Macao, were reduced to the same rate as the cable stations, viz., 7s. per word.—The Great Northern Telegraph Company make a similar notification.

The Madras Electric Tramways.—It is proposed at Madras to have not one large central power station, but two, three or four smaller stations. At each of these the furnaces will be on the incinerator principle, and the Company are prepared to make away with four, five, or six hundred cart-loads of rubbish daily.

Alloys.—Prof. Chandler Roberts-Austen will commence a course of three "Cantor" Lectures on "Alloys" at the Society of Arts on Monday next, March 6th, at five o'clock. The remaining lectures will be given on the two following Monday afternoons at the same hour.

The Halifax (N.S.) Electric Trams.—The stipendary magistrate of the city of Halifax has convicted the Nova Scotia Power Company of a breach of a provincial statute in running street cars on Sunday. The judge held that the running of street cars on Sunday was a work neither of necessity nor mercy, and was therefore illegal. A nominal fine of $5 has been imposed on the Company.

Blackburn.—Mr. Rienzi Walton, one of the Local Government Board's inspectors, opened an inquiry at Blackburn Town Hall, on Tuesday morning, into an application of the Town Council to borrow £50,000 for electric lighting purposes. The Council recently issued a circular asking tradesmen if they would use electric light if introduced, and the response was so unanimous that the Council decided to adopt it at once.

Platinum.—According to statements of the Russian Mining Department, 258 poods of raw platinum were obtained from the Ural in 1891, which is about 85 poods more than in 1890. According to the price of unpurified platinum ruling at present, the total value of the productions of the Russian platinum industry in the year 1891 exceeded 1,250,000 credit roubles, while the tax thereon amounted to 40,000 credit roubles. One pood = 36lb.

Cable Interruptions and Repairs.—

Repairs.	Interrupted.	Repaired.
Aden-Zanzibar	February 20, 1893 ...	February 25, 1893

Cables actually interrupted :—

Cayenne-Vizeu	September 24, 1892.
St. Thome-Loanda*	February 17, 1893.
Gibraltar-Tangier	February 18, 1893.

* Communication with South Africa is, during this interruption maintained by the East Coast route.

High Temperature Measurements.—M. Le Chatelier, says the *Gas World*, has found a curious cause of error in the determination of high temperatures. Professor Langley estimated the temperature of the Bessemer converter at 2,000° C., because platinum appeared to melt rapidly in the flame ; but the reason of the apparent melting is that the platinum is dissolved by the fine fog or rain of steel which is carried along by the stream of vapour. Similarly, palladium appears to melt in several furnaces where, in reality, it does not melt, but is transformed, without fusion, into a spongy mass under the influence of hydrogenation or of transient oxygenation.

Shoreditch.—At a special meeting of the Shoreditch Vestry on Tuesday night a scheme prepared by Mr. E. Manville was discussed. The scheme included a supply of electricity for public and private lighting and power purposes, and the combining of the generating station with furnaces for the utilisation of the ashbin refuse of the parish. The report was unanimously adopted, and a special committee elected to carry out the work, which is estimated to cost £63,000.

German Patents in 1892.—The number of applications for patents last year was 13,126, against 12,919 in 1891, which is an increase for last year of 1·6 per cent. In 1891 the increase was 8·7 per cent., and in 1890 2 per cent. The number of patents granted in 1892 was 5,900, against 5,550 in 1891, and 4,680 in 1890, The increase for 1892 was thus 6·3 per cent., compared with 18·6 per cent. in 1891 and 6·2 per cent. in 1890. The percentage of patents granted in 1892 to applications for patents was 85 per cent., against 92 per cent. in 1891 and 87 per cent. in 1890. The number of German patents in operation at the end of 1892 was 15,825, against 14,735 in 1891 and 13,639 in 1890.

Prolongation of the Joy Valve Patent.—The petition for the prolongation of letters patent granted to Mr. David Joy, engineer, for his invention of "improvements in steam engines," dated March 8th, 1879, No. 929, came before the Judicial Committee of the Privy Council this week. Mr. Aston and Mr. Lawson were counsel for the petitioner ; Sir Charles Russell and Mr. Sutton for the Crown. Sir Charles Russell intimated that, in the opinion of the Crown, the case was one in which a reasonable prolongation of the letters patent should be granted. Lord Watson, in delivering judgment, said their lordships would humbly advise Her Majesty to extend the term of the patent in so far as it related to the inventions embraced in the second claim of the specification for a period of seven years

The Electric Railway Bills.—The following arrangements have been made for the Electric Railway Bills in Committees of the House of Commons :—Tuesday next, Waterloo and City Railway ; Hampstead, St. Pancras and Charing-cross Railway, and Brighton and Rottingdean Seashore Electric Railway. Thursday next, City and South London Railway ; Ditto (Extension of Time), Clapham Junction and Paddington and Edgware-road and Victoria Railways. The first committee consists of Sir C. Dalrymple (chairman), Mr. F. Taylor, Mr. J. W. Philipps, and Mr. C. E. Shaw. The Earl of Morley's Committee in the House of Lords considered the Baker-street and Waterloo Railway on Tuesday, and ordered it to be reported with amendments. On Thursday last week the Blackpool, St. Anne's and Lytham Tramways Bill was read a second time. A petition has been lodged against this Bill by the Blackpool Corporation.

Institute of Chemistry.—The annual general meeting of the Institute of Chemistry of Great Britain and Ireland was held on March 1st, at 30, Bloomsbury-square, W.C., the premises recently acquired by the Institute. The report of Council and balance-sheet for 1892 having been presented and approved, the Council and officers for the ensuing year were elected, and the President, Dr. William A. Tilden, F.R.S., delivered an address in which, after referring to the satisfactory progress which had been made by the Institute during the past year, proceeded to explain the new curriculum recently adopted by the Council for the training and examination of associates, and the proposals which had been brought forward by the censors with the object of regulating the professional conduct of members of the Institute. The numbers now on the register are 828 members and 109 students, as compared with 825 members and 34 students at the date of the last annual general meeting.

Telegraphy in Queensland.—We have received from our telegraphic *confrères* in Queensland their Christmas and New Year's greetings, none the less welcome for being, thanks to the post, a little late. The form they take is a pair of excellent photographic views of the exterior and interior of the Brisbane central telegraph office. The former, which, perhaps, we should

Hosted by Google

have designated the General Post Office, is an extensive and handsome building of the Italian classic type, arcaded and terraced in the manner common to Government houses in India. Judging by the aspect of the interior, these sheltered galleries and shaded colonades which grace the outside are not mere useless adornments. The time is forenoon and the season Christmas, yet the operatives are working in their shirts and trousers! We are glad to see that the spacious instrument room is fitted with electric glow lamps; and we note with interest a typewriter on one of the desks.

The Telegraph Department of the Caledonian Railway Company.—An interesting statistical statement illustrative of the development of the telegraph department of the Caledonian Railway Company has been prepared. It shows that in January of the present year the mileage of telegraphic wire on the Caledonian Railway was 10,063 miles; in 1870 the mileage was only 3,597 miles. In January last the number of telegraph block signalling, tablet, telephone, and other electrical instruments in stations, signal-boxes, &c., was 6,076; in 1870 there were only 412. The number of battery cells provided to work the railway electrical appliances is 39,700; in 1870 2,884 were sufficient. In 1892 the number of business telegrams forwarded from stations on the Company's wires was 1,106,278. These messages averaged about 20 words each, representing, at the public rate of ½d. per word, the sum of £46,120. Telephonic messages, which are not included, would bring the total up to £50,000. Train departures signalled from station to station and signal-box to signal-box are not included.

Inter-Urban Electric Cars.—"From Spokane, Wash., to the beautiful Cœur-d'Alene lake, 32 miles distant, an electric railway," says the *Street Railway Review*, "will soon be transporting the delighted citizens of that famous city." For this purpose the chief engineer of the Spokane and Cœur-d'Alene Railway and Navigation Company has designed an entirely new type of car. This car, which is about 40ft. in length, will have a seating capacity of 60 persons, with a separate compartment for baggage. A speed of 40 miles an hour on levels is contemplated, the gradients not exceeding 1 per cent., and curves also being very light. The driving wheels are 42in. diameter paper wheels with steel tyres. The smaller wheels are 30in., of same make. A 45 H.P. single reduction motor will be used on each axle. Each car and its motor equipment will weigh 9 tons. The central portion of the cars is provided with a sort of tower, from which passengers may view the country. Power will be derived from two water-power stations, one in Spokane and the other on the line 22 miles from Spokane.

The Bureau de Contrôle.—The Bureau de Contrôle des Installations Electriques, which has been started by the Syndicat Professional des Industries Electriques, is assured of an annual subsidy of £600 for two years. M. Picou, the head of the Bureau, estimates the annual expenses at £640. Subscribers to the Bureau are entitled to have their wiring and meters tested twice a year, and the causes of short circuits, &c., investigated. The following are the annual rates of subscription:—

For an installation comprising	Per lamp per annum.	Min.
Less than 20 lamps	0·50fr.	5·00fr.
From 20 to 50 ,,	0·45	10·00
From 51 to 100 ,,	0·40	22·50
From 101 to 200 ,,	0·35	40·00
From 201 to 500 ,,	0·30	70·00
From 501 to 1,000 ,,	0·25	150·00
More than 1,000 ,,	0·20	250·00

Each arc lamp is to count as five glow lamps, and each motor or dynamo as 10 glow lamps. For various extra jobs there are various extra charges. Non-subscribers will be charged for a wiring test two-thirds of their equivalent annual subscription, with a minimum of 5fr.

Railway Companies and Free Telegrams.—In answer to Mr. John Ellis, the Postmaster-General stated in the House of Commons on Monday last that the question of free railway messages had engaged his close attention. Statistics of the number of telegrams sent free of charge for the railway companies in 1871 could, he said, only be given as regards the companies of England and Wales. In the case of these companies the number sent in 1871 was 87,201; in 1892 it had risen to 1,329,531, an increase of more than fifteen-fold. During the same period telegrams of all other descriptions rose from 9,573,548 to 57,871,429, an increase of about six-fold. Negotiations had, however, resulted in the commutation of the privilege into a right to send a fixed number of messages and words per annum in the case of the Midland, and Manchester, Sheffield, and Lincolnshire Companies. Negotiations with other companies were in progress, and it was hoped that all the companies would recognise that it was desirable, in their own as well as in the public interest, to accept the principle of commutation. As regards private Bill legislation, Her Majesty's Government would, of course, watch closely any Bills introduced into Parliament tending to the extension of the privilege.

Bradford.—A Local Government Board Inquiry was held last week with reference to the application for a loan of £30,000 for the purposes of extending the electricity supply system. The Town Clerk stated that the Council had decided to extend their area of supply in all directions from the centre of the town, and the loan was wanted for the expenses of that extension. There were now 250 private consumers. There was no intention of utilising electricity for the public street lamps, as those were supplied with gas by the Gas Committee free of cost. At one time the Gas Committee was making a profit on gas of £30,000 a year, but they preferred to supply gas for nothing for the streets and charge lower prices. The Inspector pointed out certain risks in regard to the electric light, and suggested that it might have been better that it should be in the hands of a company. The Town Clerk said that was just what the Corporation did not wish. If a private company had a hand in it the company was king of the town, but the Town Council preferred that it should itself be that. It was pointed out that the works were making a profit, and the charge was only 5d. per unit. The Town Clerk added that at Leeds, where a company was at work, the charge was 8d. per unit. Mr. W. W. Wilkinson, a ratepayer, opposed the application.

Municipal Regulations relating to Electric Light Mains in Paris.—It may be interesting to note the regulations issued by the Municipality of Paris, governing the laying of wires of private electric companies. These regulations entirely prohibit the placing of wires in sewers or other underground conduits located between the kerbs, and demand the laying of such wires under the sidewalks. The materials used in the conduits must be approved by the proper municipal officers, who are also to specify the position, exterior diameter, and required depth of the conduits. The most favourable positions, near the surface of the streets, are reserved for the municipal electric light conduits. In order to avoid crossing streets to make house connections a conduit must be carried under the sidewalk on both sides of the street except in very narrow streets. Whenever a conduit crosses a street it is to be made accessible by a manhole on one side. In very important thoroughfares each side must be furnished with a manhole. If several companies are laying wires in the same street, a common conduit must be employed, the accruing costs to be shared equally between them. Electric wires of private companies are not to be carried closer than 3ft. 3in. to the front walls of houses, which space is to be reserved for the laying of municipal wires.

Blackpool, St. Anne's, and Lytham Tramways.—This Bill has been brought in by the Right Hon. Sir Matthew White Ridley and Mr. William Coddington, for incorporating a Company with a capital of £100,000, in £10 shares, with power to construct a series of tramways from the Blackpool Promenade, passing along the Lytham-road and St. Anne's-road, and terminating in Westley-street. The Bill provides that during a period of seven years after the opening of the tramways for public traffic, and with the consent of the Board of Trade, during such further periods of seven years as the Board may from time to time specify, they may be worked by electric power, or other mechanical power than steam or cable power, subject to such regulations as the Board of Trade may think fit to secure to the public all reasonable protection against danger. A penalty of £10, with £5 per day for a continuing offence, is provided for in case the company use other than animal power, contrary to order or

Hosted by Google

regulations. If other than animal power is used, the contract with the road authorities is not to be for a longer period than two years at a time, and power is given to the company to lease or purchase and work tramways belonging to the Corporation. The period for the completion of the works named in the Bill is two years.

High Frequencies from Direct Currents.—It is rumoured from America, says *Industries*, that Prof. E. Thomson has discovered a new way of producing high-frequency discharges. There is one method which, so far as we know, has not been tried yet. It was suggested by us before Tesla experiments became fashionable as a convenient method of producing Hertz vibrations continuously and regularly. A direct-current circuit has a resistance and an arc gap. In shunt to the arc gap is a circuit containing both capacity and self-induction in series, and the oscillatory current is produced in this circuit. The frequency varies inversely as the root of the product of the capacity and self-induction, and the main resistance can be adjusted to suit the circuit—that is to say, to make the current uniform from period to period, instead of having merely a succession of oscillatory discharges. Different currents of a given frequency can be produced by altering the capacity and self-induction without altering their product. The electromotive force is controlled by the length of the arc, but is, of course, greatest in shunt to the self-induction or to the capacity. Of course, this arrangement can be modified, but it seems to us, says *Industries*, to be much better than using a series of oscillatory discharges at short intervals, as is now customary with alternating transformers.

Trent (Tyrol).—The picturesque town of Trent, in the Tyrol, has for some little while been possessed of a Municipal electricity supply which presents one or two features of interest. A waterfall is, of course, the source of power. While the gas works, after ten years existence, have only succeeded in securing about 2,000 lights, the electrical works, after two years operations, have some 7,500 glow lamps, 64 arc lamps, and 30 motors of a total of 175 H.P. connected to the mains. These lamps are divided amongst no less than 1,070 customers, of whom 300 are workmen. This unusual state of things may be explained in a large measure by the still more unusual method of charging which obtains at Trent. The tariff is 10d. per "candle year." To prevent waste of current the Municipality reserves to itself the right of lamp renewals, and makes a heavy charge for the same. The charge for power is 17s. per horse-power per annum; all motors to be switched off during the hours of maximum lighting. It is said that this low price for power has attracted several small industries to the town. Latterly the Municipality has also undertaken wiring and its maintenance in return for an annual payment of 1s. 8d. per 16 c.p. lamp installed. Distribution is carried out on the five-wire system, of which complication there are now several instances in Europe, viz., Koenigsberg, Paris (Secteur de la Place Clichy), and Manchester.

The Electricity Supply Business in Madrid.—Referring to the appointment of a new manager in Madrid by the Electrical Supply Company for Spain, the *Revista Minera* states that, although the Company sells current at the high price of $1\frac{1}{4}$ pesetas per kilowatt hour (11d. per B. T. U.) the demand is fully up to the capabilities of the Company with its present installation, and it is obliged to refuse orders. The same journal estimates that should the Company double its instalment it would be easily able to increase its business to the same extent. Another paper, referring to the success of the Company, looks forward to the time when gas will have entirely disappeared from Madrid. There is great opposition to the gas company owing to what is described as the absurd charge of 40 centimos per cubic metre (about 8s. per thousand). The consumers of electric light will, in the opinion of the Madrid paper, have little reason to complain of the present charge made by the English electrical company until the gas company reduces its charge to 25 centimos per cubic metre (about 6s. per thousand). At the same time the consumers of electric light are looking forward to the time when they will be able to obtain a supply at a charge of 80 centimos per unit (7d. per B. T. U.) instead of the present charge of $1\frac{1}{4}$ pesetas. The *Economista*, referring to the subject, says consumers of light in Madrid need not look to the Madrileña Electric Light Company to help them in their efforts to obtain gas at a lower price, and remarks that if consumers understand their business they will give the most decided support to the English electrical company as being alone able to entirely drive gas in Madrid out of the field.

The Heilmann Electric Locomotive.—There has been much talk in the French technical journals, and still more in the non-technical, about an electric locomotive designed by a M. Heilmann, and in course of construction by such a sober, old-established railway company as the Compagnie du Nord. This locomotive comprises a Lentz boiler, a Brown engine and dynamos charging accumulators; these are to supply current to motors placed direct on the axles. It was, of course, inferred by the French public that the Compagnie du Nord had some "through by lightning" scheme under weigh. A very simple solution of the puzzle is, however, found in the fact that the Compagnie du Nord has in view a couple of extensions from its terminus into the heart of Paris, and has, in consequence to look about for locomotives capable of working on its suburban lines, and at the same time available for long tunnel traffic. For this purpose M.M. Francq et Mesnard have built a special type of steam locomotive. The Compagnie du Nord, however, whilst quite satisfied with its performance, decided, in view of the popular prejudice in favour of electrical methods, to build an experimental electric locomotive fulfilling the required conditions. The Heilmann locomotive is three-axled, and two 4-pole Gramme-ring 30 H.P. motors are placed with their armatures direct upon each of the two end axles. A battery of 80 Laurent-Cély storage cells is provided, weighing 14 tons, and having a total storage capacity of 148,400 ampere hours. It is not, however, proposed to run the motors entirely off the accumulators; they are merely intended to assist the generators when inclines have to be negotiated. The motor magnets are excited by a battery of four storage cells, and it is proposed to vary the speed by regulation of the excitation. A small motor, driven off the main battery, actuates the air-compressing apparatus for the brakes and whistle.

The Comparative Cost of Gas and Electricity.—Mr. J. M. Turnbull, chemist, of Edinburgh, who last winter prepared a most exhaustive report for the Edinburgh Merchants' Asssociation upon the gas supply of the city, has, says the Scotch correspondent of the *Journal of Gas Lighting*, turned his attention to electric lighting, and has begun the reading of a Paper before the Association on "The Comparative cost of Electric Lighting and Lighting by Gas." Mr. Turnbull, we are told, does everything thoroughly, and his Paper is said to be a most complete *exposé* of some of the positions taken up by the promoters of electric light. Mr. Turnbull quotes from a prospectus issued in December last of a company which proposed to undertake the supply of electricity in Coatbridge. In that prospectus, quotations were given from an address to the effect that "1lb. of coal distilled into gas will give a light of 17·2 c.p., whilst, if converted into electrical energy, it will give 48 candles with a glow light, and 288 candles with an arc light." Mr. Turnbull points out that gas is not the only thing derived from coal; and that in Edinburgh last year $26\frac{1}{4}$ per cent. of the cost of coal was returned in the revenue derived from residuals. Proceeding to compare the cost of the two lights, he finds the average charge for electricity in fifteen towns to be $7\frac{1}{2}$d. per unit. The charge for 16 c.p. for 1,000 hours, at $7\frac{1}{2}$d. per unit amounts to £1. 15s. To that figure he adds 2s. 6d. for renewals, and 1s. 6d. for hire of meter, which makes the total £1. 19s. The charge for gas of 16 c.p. Mr. Turnbull averages at 2s. 6d. per 1,000 cubic feet; and of it 5,000 cubic feet will require to be burned in 1,000 hours to produce the same light as is given by a 16-candle incandescent lamp. Edinburgh gas is of 26 c.p.; and the equivalent light by it is obtained for 3,100 cubic feet, the cost of which is 12s. Electric lighting will thus be $3\frac{1}{4}$ times dearer than gas in Edinburgh. Taking into account deterioration of the incandescent lamp, the cost for electric lighting cannot be less to the consumer than four or five times that of gas. It will be difficult, says our contemporary's correspondent, to controvert these figures.

REVIEWS.

William Gilbert of Colchester, Physician, of London, on the Loadstone and Magnetic Bodies, &c. A translation by P. FLEURY MOTTELAY. (London: Bernard Quaritch [Printers: Ferris Bros., Pearl-street, New York], 1893, 8vo, pp. liv.—368. With translator's preface, biographical memoir, and annotations.)

Of all living men none possess a wider or more comprehensive knowledge of early magnetic and electrical literature than Mr. P. Fleury Mottelay, unless perhaps Mr. Latimer Clark, the veteran telegraph engineer. And no single man could have been found better qualified than Mr. Mottelay to prepare notes and comments to illustrate, by reference to early authorities and to modern commentators, a new edition of the famous *De Magnete* of William Gilbert. It is with the notes, the biographical memoir, and the translator's preface, that the present review is concerned.

Mr. Mottelay has laid under contribution for his annotations not only such standard authorities as Humboldt, Whewell, Hallam, and Herschel, but has collated passages in obscure early writers, such as Albertus Magnus, Simon Stevinus, Joannes Taisnier, Baptista Porta, and many others. To the thoroughness with which all such authorities have been tracked down a single example will attest. Gilbert, in Chapter xiv. of Book I., dealing with the alleged medicinal value of the loadstone, refers to one Gartias ab Horto, who narrated how the Eastern Indians declare the taking of loadstone in small doses to preserve youth. Mr. Mottelay at once identifies this obscure writer with the Portuguese author, Garcia del Huerto, who wrote in 1563 on herbs and drugs, and he gives references not only to Garcia's original book, and to its subsequent Latin editions, but to the passages in it which are referred to in the work of Gilbert. He even gives the references to Garcia in the writings of Sir T. Browne (*Vulgar Errors*), of Antoine Colin, and of Hakewill. All this is most excellent. So are his notes on p. 7, on the claims of Marco Polo to be regarded as the introducer into Europe of the art of the compass. The claims of Goia of Amalfi to the invention of the compass are, however, passed without commentary. Mr. Mottelay quotes largely from Thomson's "History of Chemistry" to elucidate the obscure passages in the chapters relating to the nature of the loadstone, and from Hakewill in those that touch on the astronomical relations of the magnet. He is equally at home in making references to the alchemists and to the astrologers, as notes such as those on the Metonic cycle, on p. 351, show.

Amid such a wealth of erudition it is no wonder that there arise obscurities. In the note on p. 2 relating to the alleged effect of diamonds in counteracting magnets, a passage of ten lines and-a-half is put into quotation marks, of which only the half is quoted from Rohault's "System of Natural Philosophy," the remainder being apparently Mr. Mottelay's own reference to other authors. Again, on p. 15, apparently following Whewell, Barlowe's rare work of 1597 is referred to as Barlowe's "Supplement." Whewell's inaccurate translation of the word no doubt arose from his ignorance of the existence of Barlowe's volume bearing the title of "The Navigator's Supply." It was also unknown to Ronalds.

There are a few errors for which the printer's devil must be blamed. The author of the Cyclopædia was Abraham Rees not *Ree* (p. x.). The famous collector of electrical books was Sir Francis Ronalds, not *Ronald* (p. 9). The Latin name of Amsterdam is not *Amstelrodami* (p. 357). The eminent scholar and critic, Jan Gruter, who is said to have edited Gilbert's "Philosophia Nova" in 1651 (p. xxv.), died in 1627. The pole that points northward is not called by the French the *astral* (p. 283), but the austral pole. Sir John F. W. Herschel is not properly described as *F. W. Herschel* (p. 365). The author of "The Theoriques of the Seven Planets" was not *Blunderville* (p. 363), but Blundevile. The date of Barlowe's "Magneticall Aduertisements" is 1616 (the first edition), though 1618 is given on p. xiv. as the date of the preface to the book. The Nicolas Cabeo mentioned on p. 9 is, of course, the same as the Nicolao Cabeo quoted elsewhere, and as the Cabaeus mentioned on p. xix. The English mathematician referred to by Humboldt was not Edward *Knight* (p. xl.), but Edward Wright. But these are trifling inaccuracies, for which one cannot hold so accomplished and erudite a scholar as Mr. Mottelay to be responsible. Neither is he responsible for the unfortunate circumstance that the cut of Gilbert's house at Colchester on p. xi. is reversed right for left—for the cut seems to have been reproduced (though nothing is said about it in the letterpress) from Dr. Richardson's article in the *Asclepiad*, which has the same defect.

Mr. Mottelay has further enriched his edition with a (reduced) facsimile of the title-page of the folio edition of 1600, and with those of the two later editions of 1628 and 1633, as well as with the title-page of Gilbert's posthumous work, "De Mundo Nostro." A point of novel interest arises respecting the engraved title-page to the edition of 1828. As reproduced (on p. 359) the last line before the date is simply the word *Authoris*. In the copy which has been for many years in my possession this word does not appear, and instead there has been engraved the name *Joh: Hallervordij*. In other respects the plate is precisely the same. This change of publisher's name on the title-page does not, of course, constitute a separate edition. Otherwise the copies of Mr. Mottelay's book that bear on the title-page the name of Mr. Bernard Quaritch would have to be regarded as of a different edition from those that bear the name of Messrs. John Wiley and Sons. With respect to the "facsimile" title-page of the "De Mundo Nostro," it is technically not such, since all the lines of the original, both those printed in scarlet as well as those printed in black, are there reproduced in black. In all other respects it is an excellent reproduction.

The biographical memoir which Mr. Mottelay has drawn up embodies, without adding a single new fact to those already known, a readable summary of Gilbert's life. It quotes considerably from the biographical notes which Mr. Conrad Cooke contributed three years ago to the columns of *Engineering*.

Mr. Mottelay does me the honour to refer to me in his notes. He accredits me on p. 283 with having introduced the term "north-seeking" pole to avoid the ambiguity of the commoner "north"-pole. The term did not, however, originate with me: I learned it from my master, the late Prof. Guthrie, who did not (so far as I know) claim to be its originator. I certainly have never claimed to have invented the term. Mr. Mottelay quotes from my monograph on Gilbert (written in 1890, not 1891) some remarks about the supposed handwriting of Gilbert, and comments on my not having seen a notice, in a second-hand catalogue of 1889, of an inscribed copy of *De Magnete*, the same from which the title-page has been reproduced by Mr. Mottelay in reduced facsimile. It happened that I did not hear of this copy until it had passed into the hands of Mr. Chas. L. Clarke, of New York, who very courteously wrote me about it, and subsequently had the kindness to send over to several British members of the Gilbert Club photographed facsimiles, and the negative from which they were produced. It is a matter of congratulation to all Gilbertians to find that the handwriting of this inscription is in accord with that of the other known inscribed copy.

There is but one single passage in the whole of Mr. Mottelay's editorial addenda that I could wish otherwise than it is, or would pronounce unsatisfactory: it is the part on pp. xix. and xx. relating to the various editions of *De Magnete*. Of these I maintain that there are three—those of 1600 (London), and of 1628, 1633 (Stettin),—copies of which have been in my possession for many years. Mr. Mottelay quotes other writers as speaking of four or five editions, and himself says, "Thus there are eight distinct editions referred to." This is entirely misleading. The alleged 1600 Amsterdam has never been seen. Ronalds evidently did not believe in it. Kuhn's reference to it is doubtless an error for the London folio of 1600. The alleged Frankfort editions of 1629 and 1638 were never heard of before the mention of them in the biographical note in the ninth Encyclopædia Britannica; and I have in vain challenged the author of that note to produce any such editions. They are quite unknown in Frankfort. The "five editions published in Germany and Holland before 1628" which Professor Robison stated that he had

Hosted by Google

"seen" are utterly unknown in Germany and Holland; and his alleged second British edition is equally unknown to *every* other writer. Lastly, the supposed eighth edition "Republished at Ferrara in 1629 with a commentary by Cabaeus" is nothing else than the *Philosophia Magnetica* of the Jesuit Father, Nicolao Cabeo, to which Mr. Mottelay himself makes such frequent reference in his footnotes, which was published at Ferrara in 1629, and consists mainly of a commentary on the "original work," that is to say, on the original researches of Gilbert, and in which many of the cuts even are reproduced. There are more than forty existing copies known of the *De Magnete*: amongst these there are but the three editions. If Mr. Mottelay can discover a fourth I shall be the first to congratulate him. No doubt it is a generous view to credit all the mistaken references of prior writers with being immaculate: but it leads to their being repeated again, if quoted without a hint of their doubtful character. As to the two Stettin editions, Mr. Mottelay is equally generous to the well-intentioned writers, whose scholarship was insufficient to enable them to distinguish, as Mr. Mottelay does with so much pains, between Sedini, Sedani, and Seduni, which are as remote from one another as Stettin, Sedan, and Sion (in Valais). But is not generosity misplaced where it quotes as of weight the uncritical writers who confused these names together?

In all the above it will be noted that, for reasons that will be appreciated, not one word has been said as to Mr. Mottelay's translation itself. Of that others must be left to judge. I will only remark that, without saying anything in praise or dispraise of the text for which Mr. Mottelay is responsible, the book comes as a surprise and a pleasure. The paper and print are alike far superior in quality to the vast majority of electrical books, whether English or American; and if we except the rather unfortunate reproduction of Clamp's engraved portrait of Dr. Gilbert, the reproduced illustrations are also well and satisfactorily executed. So that Mr. Mottelay may be congratulated on the high degree to which he has realised his own expression of hope, quoted from Gilbert himself, that his efforts will "find the heartiest approval among all intelligent men and children of magnetic science."

SILVANUS P. THOMPSON.

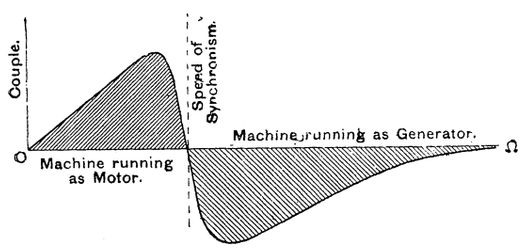
THE BROWN AND HUTIN-LEBLANC ALTERNATE CURRENT MOTORS.

In *The Electrician* for January 27, 1893, Mr. C. E. L. Brown described a non-synchronous motor for ordinary alternate currents, the principle of which was based upon the following phenomenon observed by the inventor:—

A conductor placed in an alternating field, and set rotating with a certain velocity, will increase its velocity to practically synchronous speed, and has a tendency to keep to this speed against a load. Currents are induced in the conductor by the alternating field, which, so long as the conductor is at rest, are neutral as regards their effect on the inducing field, and give rise to no twisting couple. But as soon as the conductor is set in motion this condition ceases, a turning moment is produced, the value of which increases as the speed rises till synchronism is nearly attained. The direction of rotation of such a motor is quite indeterminate, as the conductor tends always to synchronous rotation in the direction in which it was first set in motion. Several methods of making a motor on this principle are described by Mr. Brown in the article referred to. These motors have, like the Tesla and multiphase motors, the advantage of being non-synchronous, but, unlike these motors, they are not self-starting.

Shortly after the publication of Mr. Brown's article, MM. Hutin and Leblanc claimed priority for the discovery and application of this principle; and, in the current number of our contemporary, *La Lumière Electrique*, they refer to former articles by them in that journal, in which they state that the complete explanation was given as long ago as May 30, 1891. The articles in question are highly mathematical in character, but the chief result of their work appears to be as follows:—Imagine a machine with an even number of magnet poles, the magnetising coils being so wound that a steady current flowing through them would magnetise the poles alternately north and south. Let the armature, which is to be the movable part of the machine, be provided with two sets of coils, the coils in each set being as numerous as the pole pieces of the machine, and being wound alternately in opposite directions in the usual manner. Also suppose the coils of the first set to be situated on the armature half way between those of the second set, so that if the machine were used as an alternator with a double-wound armature the electromotive forces in the two armatures would differ in phase by a quarter of a period.

In order to use such a machine as an alternate-current motor, MM. Hutin and Leblanc propose to pass an alternating current through the *field magnets* after short-circuiting each armature circuit. If the armature be revolving with an angular velocity Ω, it is shown that the mechanical power developed by the motor is a complicated function depending on Ω, the frequency of the alternating current through the magnets, the resistance and self-induction of each armature, and the number of field-magnet poles. This power is fairly proportional to the speed of the motor Ω until synchronism is nearly attained; it then falls off, and becomes negative, the machine acting as a dynamo. A curve (reproduced) is given by MM. Hutin and Leblanc, showing how the power developed varies with the angular velocity Ω of the



machine. With the object of obtaining a more constant turning moment, the writers propose to double the number of the field magnets, forming a double set corresponding with the two sets of armature coils. Two alternate currents round the field magnets are then required, the phase of one current being different from that of the other, and under these circumstances the writers assert that the turning moment is more constant.

WHAT IS A DYNAMO MACHINE?

BY J. A. KINGDON.

Recent and threatened patent litigation render the answer to this question one of considerable commercial importance. The term dynamo machine, or, shortly, dynamo, is used in one or two different senses, sometimes being restricted to electro-magnetic generators which excite themselves, while sometimes it is understood to include all classes of electro-magnetic generators, and occasionally it is taken to mean electro-magnetic apparatus in general, and to include motors, dynamotors, and induction coils as well as generators. It is not unlikely that the ingenuity of expert witnesses and leading counsel may be exercised to prove that a dynamo is not only a machine for transforming mechanical energy into electrical currents, but that the term includes any source of electricity such as primary or secondary batteries, and thermopiles, and attempts may even be made to give the word a still wider meaning. It therefore becomes important to the electrical profession to ascertain exactly the meaning of the term dynamo machine, both in the exact scientific sense and also in the popular sense, and it would be a matter of satisfaction if the term were authoritatively defined in the same way as the different units—*e.g.*, volt, ampere, ohm, and watt—at an International Congress, such as is likely to be held at Chicago thi year.

Hosted by Google

It is probable that the term was first introduced by the late Dr. Werner von Siemens in January, 1867, when he described the first self-exciting continuous-current machine to the Berlin Royal Academy of Science.* After describing the manner in which a small amount of residual magnetism may be used to induce currents, so as to excite the field magnets of the machine more strongly, Dr. Siemens continues, "The action described must occur, indeed, with every electro-magnetic machine which is based on the attraction and repulsion of electro-magnets, the coils of which are included in its own circuit, still special considerations are required to construct such *electro-dynamic* machines of great power."† The term dynamic electricity appears to have been used about this time to denote continuous currents of electricity as distinguished from static charges and perhaps vibratory currents. At all events, whether it was introduced by Dr. Siemens or no, the term dynamo-electric machine began to be used within a few years of 1867 to describe a machine by which continuous currents were generated by means of mechanical power.

In 1875, in a paper by S. C. Tisley, in the *Journal* of the Society of Telegraphic Engineers, Vol. IV., on a "New Form of Dynamo-Magneto Electric Machine," the author states that, "The armature is constructed specially to prevent the accumulation of heat, to which every class of *dynamo machine* is liable." The drift of the paper indicates that the author referred to a self-exciting machine for generating continuous currents. The illustration shows a small dynamo to be driven by hand through a jack-in-the-box gearing. In 1876, Edward Weston, in the United States Patent Specification No. 182,977, alludes to "That class of machines, known as dynamo-electric machines in which currents induced in a revolving armature are passed round the electro-magnets, strengthening the magnetic field, this, again, increasing the strength of the induced currents in the armature, and so on, until a maximum is reached." There is no doubt that in the early years of electrical engineering the term dynamo was applied to a machine which excited itself through the cumulative action and reaction between the armature and field magnets, and that a dynamo was regarded as a different machine from either a magneto machine with permanent steel magnets or a separately excited machine, such as Wilde's, described to the Royal Society in 1866 (*Phil. Trans.*, Vol. 157, p. 101). In later years the term came to include all classes of machines for transforming mechanical energy into electrical energy by the displacement of conductors in magnetic fields, and it has also been taken to include electromotors.

A few years ago Mr. Mordey introduced the very convenient and expressive term "alternator" to describe machines for generating alternating currents, and this name is coming gradually into general use. It will be generally admitted that a short word denoting simply and solely a "*continuous-current machine*" would be very convenient. It is unlikely, however, that electrical engineers would look with favour on the introduction of a new term to describe a perfectly well-known machine. But if the term dynamo machine were restricted to its original meaning of a continuous-current self-exciting machine, it would probably soon be recognised as a great convenience, as well as being scientifically more accurate.

With a view of eliciting criticism and suggestions the writer ventures to submit the following definitions:—

1. A Dynamo Machine is a self-exciting machine for transforming mechanical energy into electrical energy by the generation of continuous currents.

2. An Alternator is a machine for transforming mechanical energy into alternating current electrical energy.

3. An Electromotor is a machine for transforming electrical energy into mechanical energy.

The term electro-magnetic generator might be used to include both dynamo machines and alternators, and these as well as dynamotors and induction coils would all be comprehended in the general expression—electro-magnetic machinery.

A DOUBLE POLE VOLTMETER SWITCH.

The accompanying sketch shows a very simple, easily constructed, and exceedingly convenient double-poled voltmeter switch, designed by Mr. Malcolm Sutherland, for testing secondary batteries, &c. It consists of a split brass ring, a number of brass clips, or contact pieces, and a vulcanite arm with a handle. The number of clips depends on the number of points at which it is required to measure the potential. The

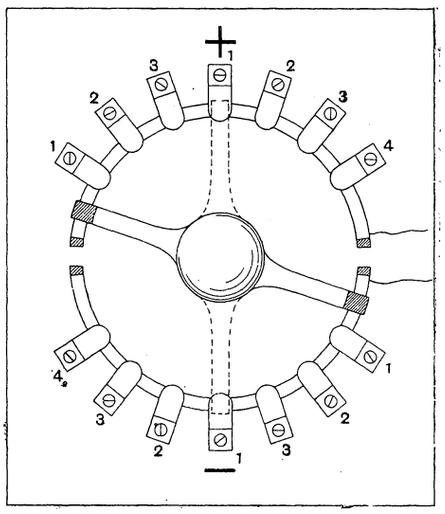

illustration shows one which was made to read the voltage of three sets of accumulators and four circuits. The wires from the voltmeter are connected, one to each half of the ring, and the wires from the cells and circuits are brought to the clips which are ranged round the ring. The clips are clear of the ring, and as long as the arm is in the position shown in the sketch the voltmeter is entirely disconnected from the cells and circuits. When it is necessary to take a reading, all that has to be done is to turn the handle, so as to bring the brass contact pieces between the ring and the clips Thus the dotted line shows the arm in position for taking a reading from circuit No. 1.

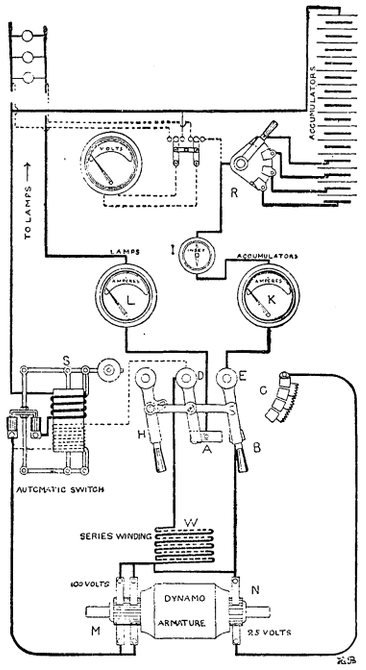
THE SCOTT-SISLING SYSTEM FOR COUNTRY HOUSE LIGHTING.

Small plants for private house lighting and similar purposes are rapidly increasing, and it is important that they should be arranged so that their operation is simple and efficient in practical work. A battery is naturally antagonistic to these conditions, owing mainly to the fact that it requires a considerably higher pressure for charging than it will give when discharging, whilst its expense generally necessitates the use of the smallest size which will answer everyday requirements. The generating plant has, therefore, frequently to run for long hours at light load to charge the battery. Various devices have been adopted to avoid this. In central station work, probably, the best way is to use a small dynamotor, driven from the main, the secondary being put in series with the battery circuit to give the extra pressure required for charging. This arrangement is used at Liverpool and elsewhere. Another device, which is more clumsy and expensive, consists in the use of larger cells at one end of the battery, so that the full dynamo current may be sent through them without injury, after which the greater part of the current is taken off to the lamps, while the smaller portion charges the smaller cells of the battery. Neither of these devices is suitable for a private plant, and for this reason Messrs. Laurence, Scott and Co. (Limited), of Norwich, have introduced an arrangement known as the Scott-Sisling System. This has been already described in *The Electrician*, Vol. XXVII, p. 556, but one or two improvements, recently introduced, deserve further notice.

Hosted by Google

A special dynamo is used, having two windings on its armature and two commutators. The lamp current is taken from the principal commutator through series coils on the dynamo magnets, thus securing the advantage of constant driving speed which is not often associated with the use of accumulators. The battery charging current is also taken from the principal commutator, but through the extra winding on the armature



A is connected to lamp main through the ammeter L. B is a contact for running cells in parallel with dynamo. C is the contact for charging cells. It is divided into sections connected by resistances. D is the dynamo switch. H is the handle for closing dynamo switch. E is the battery switch connected to cells through the current index I, and the ammeter K. R is the regulating switch for adjusting the number of cells in circuit. W represents the series winding of dynamo.

FIG. 1.—Diagram of General Arrangement of the Scott-Sisling System.

instead of through the series coils on the magnets, so that its pressure is increased, whilst there is no risk of the dynamo being reversed. The arrangement is shown in Fig. 1, and it will be seen that the switches, shown on a larger scale in Fig. 2,

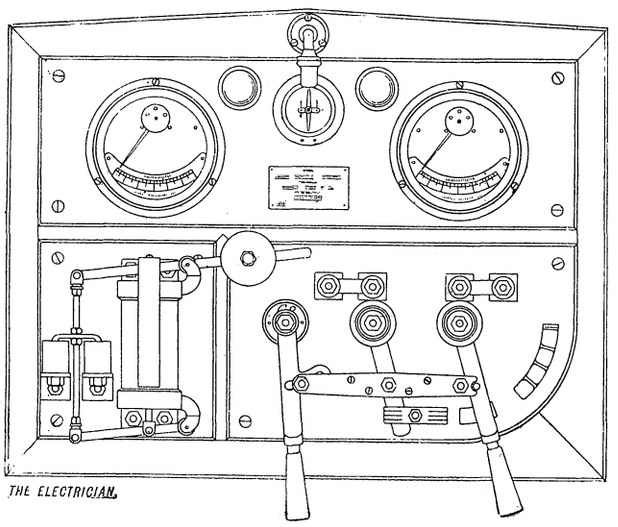


FIG. 2.—Switchboard for Scott-Sisling System.

are interlocked in such a way that the battery is always connected to the dynamo *inside* the compound winding, whether it is being charged or discharged to assist the dynamo. In the latter case, the battery current traverses the series coils of the dynamo, so as to strengthen its field, thus tending to minimise the discharge of the battery so long as the dynamo is able to give the output required.

The usual procedure with this arrangement is to start the dynamo about dusk and use its spare power for charging the battery. As the load increases towards the full output of the dynamo, the charging current is first diminished and then stopped, the battery being coupled to the principal brushes of the dynamo ready to discharge if neccssary. As the load falls off the charging is again commenced and increased as spare power becomes available, thus maintaining an almost steady load and a good average efficiency with a proportionate shortening of the hours of running. Messrs. Laurence, Scott and Co. inform us that this arrangement is in use in several country houses, and is operated without trouble by the regular engine-driver or carpenter on the estate.

THE CHRISTIANIA CENTRAL STATION.

(COMMUNICATED.)

The Christiania three-wire station came into operation on December 13th last, when certain streets were lit up. The electrical station was decided upon in April, 1891, and 500,000kr. were voted towards the undertaking (1kr. = 1s.). The response to the circular invitation was, however, so large that the plans had to be materially extended, and they finally involved an estimated expenditure of 1,165,000kr. The station capacity amounts to 24,000 lamps of 8 c.p., with a cable network sufficient for 40,000 lamps. Power is supplied by four compound condensing direct-coupled engines, two of 600 h.p. each, and two smaller ones respectively 260 h.p. and 130 h.p. Only a small battery of accumulators has been installed. It has a capacity of 685 ampere hours at 240 volts, that is to say, an output of 154,800 watt hours. This battery will thus be able to supply current to 774 incandescent lamps for four hours. It will be seen that this battery is comparatively small, but it is only intended for night and midday service and as a reserve. The station is in a central position, the maximum radius of the area of consumption being about half a mile. Twelve main feeding cables proceed from the station to a corresponding number of points of distribution. The cables are lead-covered, made by Messrs. Felten and Guillaume, and are laid directly in the ground in a layer of fine sand, covered with a layer of bricks. The contract stipulated for 15 megohms per kilometre of cable laid, immediately after laying, and at least 5 megohms per kilometre during working and after the lapse of a year. At the test, when all the cables, large and small, were laid, the insulation resistance of the whole network was about 8·6 megohms. The following cables have been laid :—Main cables, 19,600 metres ; distributing cables, 32,500 metres ; service cables, 5,000 metres ; street-lighting cables, 6,700 metres—in all, some 64 kilometres, or about 40 miles. Hence the insulation resistance, after laying, was about 550 megohms per kilometre ; or 343 megohms per mile.

In the boiler-house there are at present three Babcock and Wilcox boilers, with an aggregate heating surface of 645 square metres These are guaranteed to have a normal capacity of 14 kilogrammes of water per square metre of heating surface, so that the three boilers can give 9,030 kilogrammes of steam per hour, which, with forced draught, can be increased to 11,610 kilogrammes per hour. The guarantee for the steam engines is a normal steam consumption of 7·3–8·5 kilogrammes per indicated horse power per hour, according to size. Worthington pumps are used for feeding the boilers. In the basement under the boiler-house there is a reserve water tank, holding 15 cubic metres (3,300 gallons). Before entering the boiler the feed water is passed through an economiser. Coke is used as fuel, and with ordinary working the boilers are guaranteed to evaporate eight kilogrammes of water for a kilogramme of coke, the steam pressure being ten atmospheres (147lbs. to the square inch). The condensing water is taken from the harbour through a pipe 300 metres long and 400 millimetres in diameter. The steam-engines have been supplied by G. Kuhn, of Stuttgart, and the electrical equipment proper has been done by Messrs. Schuckert and Co., of Nüremberg. The accumulators (Tudor) are from the Accumulator Company of Hagen (Wiesbaden).

Hosted by Google

The 14-ampere street arc lamps, 40 in number, are of Schuckert make, and are distributed in six streets or squares. The lamps are run off the distribution cables in the streets, and the regulators are placed in wooden boxes, fixed on to the nearest house wall. The price of the kilowatt hour is 75 öre (10d.), and the current consumed is measured by Aron and by Schuckert meters. The dynamos are multipolar shunt machines; the two largest having 14 poles each, the next two have 12 each and the smallest 8 poles. The two large engines run at 110 revolutions, the two small ones at 150 and 170.

It may be mentioned that the latitude of Christiania being 59° 56′ N., its daylight curve is exactly the same as that of St. Petersburg which appeared on p. 476 of *The Electrician* of February 24th. Thus in summer time the sun is below the Christiania horizon for six hours only (9 p.m.—3 a.m.), but in January it sets about three in the afternoon, and does not rise again until past nine o'clock, that is to say, the night is 18 hours long; a variation of 200 per cent., which can hardly be conducive to economy.

THE MOISSAN ELECTRIC FURNACE.

M. Henri Moissan makes some more interesting announcements in the last number of the *Comptes Rendus* with regard to the latest results obtained by means of his electric furnace.

At ordinary temperatures the oxides of uranium are practically irreducible, but they have yielded to the heat of the electric furnace. M. Moissan prepares a mixture of uranic oxide ($U\ O_3$), and of the green oxide of uranium (U_3O), adding a little powdered carbon and strongly compressing the whole. Placed in M. Moissan's furnace, and exposed for a few minutes to a current of 450 amperes at 60 volts, one can obtain a metallic ingot, the pieces of which, if agitated, will emit sparks from the combustion of traces of foreign matter. The yield of uranium is fairly good, from 200 to 220 grammes may be obtained in twelve minutes, the average composition of the ingots being 90 per cent. uranium and 10 per cent. carbon. These carbides of uranium slowly decompose water at ordinary temperatures, and their melting point is much higher than that of platinum (1,780°C.).

Chromium and manganese have also been prepared by M. Moissan. Pure protoxide of manganese is mixed with carbon and exposed to 300 amperes at 60 volts, and in five or six minutes there is at the bottom of the crucible an ingot of carbide of manganese (89 per cent. manganese), weighing 100 to 120 grammes. With less power smaller quantities can be obtained in a little longer time. If the reduction is effected in presence of an excess of oxide the percentage of carbon is greatly diminished, and in some samples it is possible to get 95 per cent. manganese. When the proportion of carbon is small, the metal may be easily preserved in an open vessel, but as soon as the proportion of carbon increases the humidity of the air decomposes the substance.

A mixture of calcined sesquioxide of chromium and carbon is reduced in eight to 10 minutes by a current of 350 amperes at 50 volts, leaving an ingot weighing 100 to 110 grammes adhering to the crucible. The average composition of M. Moissan's samples was about 89 per cent. chromium, and the rest carbon. By a further attack in the furnace practically pure chromium may be obtained. Not only may the sesquioxide be reduced in this way, but also the natural chrome iron ore $Fe,\ O,\ Cr_2,\ O_3$.

BOVET MAGNETIC ADHESION APPARATUS.*

BY R. V. PICOU.

The adhesive force which comes into play between two pieces of iron forming part of the same magnetic circuit has up to the present received but a limited application. It has only been utilised in a few lifting machines, and the necessity for slinging the pieces of iron to be transported from one place to another in this way avoided, and in a few drills which it thus became unnecessary to bolt down to the objects to be drilled, such as armour plates and ships' hulls. Magnetic adhesion, nevertheless, seems destined to render valuable services to industrial mechanics.

A few months ago, whilst studying a mechanical problem in which electricity seemed to have no likelihood of taking part, M. A. de Bovet, Manager of the Compagnie de Touage de la Baisse Seine et de l'Oise, hit upon and carried out one of the most remarkable applications of electricity, utilising it in connection with chain-towing. All the riverside population of the Seine know "the chain," and have seen the boats of the Company hauling themselves along by means of a chain running along the bottom of the Seine from Paris to Rouen. Without going into details as to the reasons which have gradually resulted in the Company's material no longer being in touch with the state of things which has been brought about by long years of work on the Seine, suffice it to say that the desideratum in the Company's new boats was that they should work with short lengths of chain. The old craft, which made use of natural adhesion, required enormous lengths of chain. All manner of mechanical and hydraulic solutions had been considered, but they only secured the desired result at the risk of grave inconveniences. M. de Bovet, who had long been familiar with the resources of electricity, had the happy idea of employing it as panacea to cure all his ills. It is only right to say, however, that, with a prudence which the prevailing uncertainty justified, he, at first, only argued the matter out somewhat as follows: However small the increased adhesion obtained by magnetisation may prove to be, it will in any case enable me to reduce the length of chain taken aboard; and that is an advantage the exact magnitude of which it is worth experimenting upon to discover.

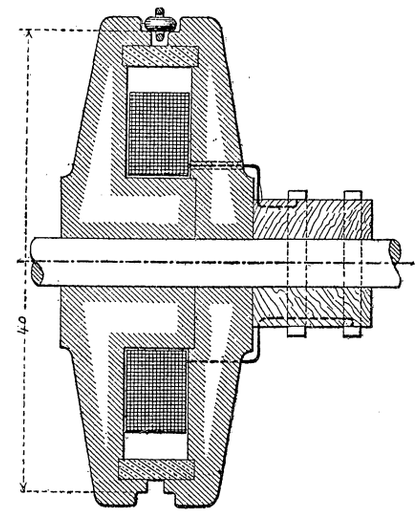

FIG. 1.—Bovet Magnetic Pulley for Chain Towing.

First of all a small cast-iron pulley was constructed, and then a large, soft steel pulley of the general shape shown in Fig. 1. The towing chain is, it will be seen, employed to complete the magnetic circuit of a rotating electro-magnet.

It is difficult to calculate the probable effect *a priori*. First of all the chain is not absolutely comparable to a cord rolled round a drum. Then the magnetic effect is somewhat difficult to bring into a formula, so long as it is not known exactly what terms it affects. However, all this, notwithstanding, experiment showed that the idea was a good one, and that a pulley 1·2m. in diameter embraced for two-thirds of its circumference, gave a towing effort equal to that of an angle of embrace of 5π or 6π in the case of the smooth pulleys, 1m. in diameter, used in the old boats. A tow-barge, named the Ampère, was ordered and constructed, and recently came into operation.

In the course of his investigations, M. de Bovet was struck with the number of applications which might be made of magnetic adhesion on the condition that it was systematically studied, and all doubts as to the magnitude of the effects obtainable were removed from the minds of its many opponents. Amongst other applications, that of couplings may be noted. The problem is one well known to mechanical engineers and the multitude of methods which have been proposed is a proof that none of them completely fulfilled the conditions of the problem. When it is a question of transmitting small powers friction is generally used. For large amounts of power friction must be given up, and recourse had to claw clutches; but these have the great defect of not being operable during working, and when this condition is imperative as in certain apparatus, such as variable speed rollers, the problem is almost insoluble.

* From *L'Industrie Électrique*.

Hosted by Google

The Bovet coupling (*see* Fig. 2) affords a complete and perfect solution of the question, and possesses marked advantages over its mechanical congeners. It consists of a block A in cast or wrought iron, around the face of which a groove is made, in which the wire B is placed. It terminates in rings *a b*, on which brushes bear. The whole is keyed to the power shaft. The shaft to be clutched is provided with a block F, capable of sliding along and approaching *c d* until it is in contact. It follows, therefore, that when the wire B is traversed by a current, F is attracted against *c d*, and participates in the motion of A. The chief advantage of the system resides in the fact that, contrary to that which takes place with all kinds of friction clutches, adhesion is obtained without any external reaction. The magnetic forces in a closed circuit are all internal, and there is no thrust on the journals nor reaction of

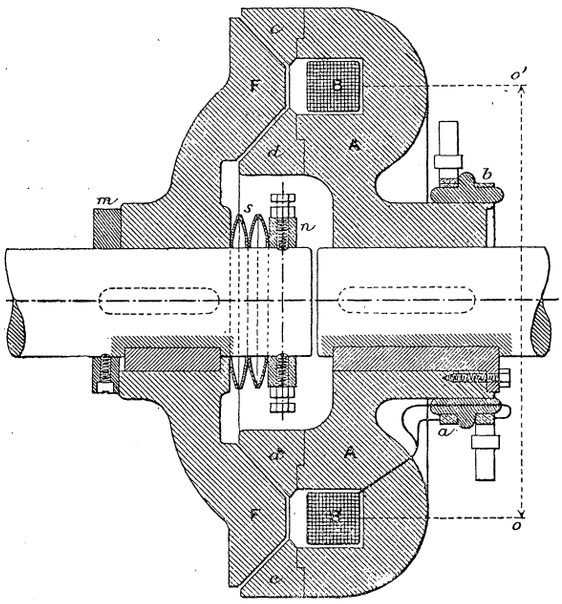

FIG. 2.—Bovet Magnetic Clutch.

elastic parts on supports. It will be observed, that the magnetic circuit is cut across in the shape of a wedge. This is another very important point, which gives the apparatus the valuable property of limiting the maximum transmitted effort, and permitting slipping when this amount is exceeded. Experiment shows that if the resisting effort becomes too great A slips, but does not release F. This property enables one to entirely avoid injury to apparatus connected to F, such as chains, gearing, &c., since it is only necessary to regulate the value of the current in order to ensure that the required maximum effort is not exceeded. If the contact surfaces of A and F were flat, the same result would not be attained; there would no longer be merely slipping, but complete disconnection, which might often give rise to grave inconveniences.

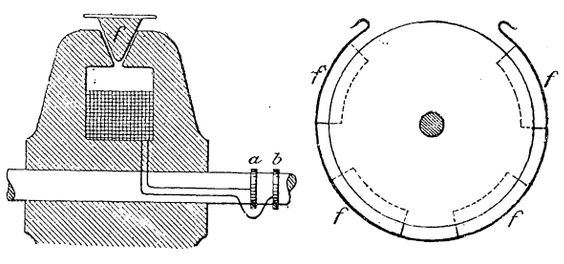

FIG. 3.—Bovet Magnetic Railway Brake.

With very small dimensions this clutch can be used for very large powers. A 400 or 500 H.P. clutch running at an average speed is only 1m. in diameter.

All these qualities open a vast field for the application of such apparatus. One field is the braking of railway trains. Here the great advantage results from the simultaneous action of all the brakes due to the instantaneous propagation of the current from one end of the train to the other. The low price of the apparatus, the small expenditure of energy, and its complete adaptability are so many things in its favour, to which may easily be added, if necessary, automatic action in case of uncoupling of carriages.

Several forms of brakes have been devised by M. de Bovet. In most of them the brake is not applied to the rim of the carriage wheel, but to the circumference of a special wheel carried on the axle, the general shape of which recalls that of the tow-chain wheel. The groove, however, is cut V-shaped (*see* Fig. 3), instead of having the special shape required by the chain. The brake shoes *f* are wedge-shaped, and are fixed to a steel band, the normal tension of which keeps it a little way away from the wheel. This band is fixed to the body of the carriage after having embraced the brake wheel for an angle of from 1800deg. to 270deg., according to the character of the carriage. When a current passes, the wheel is magnetised and attracts the shoes, which make contact. The pressure exerted only depends upon the value of the current, and varies with it within very wide limits. In addition, the apparatus acts as a band-brake, and gives a direct pressure, at least in the case of the first shoes, much superior to that corresponding to the current strength. Moreover, the apparatus appears to possess considerable power and flexibility.

In closed magnetic circuits, such as those we are concerned with, the expenditure of electric energy may be extremely small, so that a small source of current, such as a few accumulators for instance, is enough for a number of operations. Automatic action in case of rupture of coupling is easily obtained by means of an auxiliary wire, which, traversed by a small current obtained from the accumulators, actuates the electro-magnetic apparatus in the guards' vans commanding the main circuit. So long as the current is flowing these electro-magnetic devices keep the main circuit open and the brakes free. If a carriage coupling breaks, the auxiliary current being interrupted, the brakes are thrown into action in front and behind. The two halves of the train are thus automatically braked from the battery in its guards' vans. The different brake-wheels being all in parallel, the rupture of the main circuit does not in any way interfere with the working of the apparatus.

These few remarks are only a glance at a few of the applications of magnetic adhesion. There are many others, only touched upon as yet.

MEETINGS OF SCIENTIFIC SOCIETIES, &c.

(TO-DAY) FRIDAY, March 3rd.

INSTITUTION OF ELECTRICAL ENGINEERS.

8 p.m. Students' Meeting. Paper to be read: "The American Experiences of an Embryonic Electrician," by J. M. Barr.

OLD STUDENTS' ASSOCIATION.

8 p.m. Meeting at the Central Institution. Lecture "Mountaincraft," by Clinton T. Dent (illustrated by lantern views).

ROYAL INSTITUTION.

9 p.m. Evening Discourse. "Sculpture considered apart from Archæology," by George Simmonds.

SATURDAY, March 4th.

ROYAL INSTITUTION.

3 p.m. Afternoon Lecture: "Sound and Vibrations," by Lord Rayleigh, F.R.S.

JUNIOR ENGINEERING SOCIETY.

3 p.m. Ordinary Meeting at the Westminster Palace Hotel. Papers to be read and discussed: (1) "Expansion Curves," by W. J. Tennant. (2) "Feed-Water Heaters," by Walter H. DeRitter.

MONDAY, March 6th.

ROYAL INSTITUTION.

5 p.m. General Monthly Meeting.

SOCIETY OF ARTS.

5 p.m. Cantor Lecture (1): "Alloys," by Prof. W. Chandler Roberts-Austen, F.R.S.

SOCIETY OF ENGINEERS.

7:30 p.m. Ordinary Meeting, at the Town Hall, Westminster.

TUESDAY, March 7th.

INSTITUTION OF CIVIL ENGINEERS.

8 p.m. Ordinary Meeting. Paper to be read, with a view to discussion: "On Plant for Harbour and Sea Works," by Walter Pitt, M.Inst C.E. At this meeting the monthly ballot for members will be taken.

WEDNESDAY, March 8th.

SOCIETY OF ARTS.

8 p.m. Ordinary Meeting. Paper to be read: "Music in Elementary Schools," by W. G. McNaught.

THURSDAY, March 9th.

INSTITUTION OF ELECTRICAL ENGINEERS.

8 p.m. Ordinary General Meeting. Paper to be discussed: "Notes on Testing Alternators," by W. M. Mordey.

FRIDAY, March 10th.

PHYSICAL SOCIETY.

5 p.m. Papers to be read: (1) "The Application of Lagrange's Equations of Motion with especial reference to a Perforated Solid in a Liquid," by Dr. C. V. Barton; (2) "On the Magnetic Field of a Circular Current," by Prof. G. M. Minchin, M.A.; (3) "On the Differential Equation of Electrical Flow," by T. H. Blakesley, M.A.

ROYAL INSTITUTION.

9 p.m. Evening discourse: "Early Myth and Late Romance," by Sir Herbert Maxwell, M.P.

Hosted by Google

The Electrician.

Published every Friday, Price Fourpence; Post Free, Fourpence Halfpenny.
Editorial, Publishing, and Printing Offices :

SALISBURY COURT, FLEET ST., LONDON, E.C.

Telephone No. 2714. *Telegrams :* "ELECTRICIAN NEWSPAPER, LONDON."

All Letters relating to Subscriptions, Advertisements, and other business matters should be addressed to the Publisher, "THE ELECTRICIAN," *Salisbury-court, Fleet-street, London, E.C. Cheques and Money Orders should be made payable to* "THE ELECTRICIAN" *Printing and Publishing Company, Limited, and be crossed "Coutts and Co."*

All Editorial letters to be addressed to the Editor.

All letters intended for insertion in "THE ELECTRICIAN," *or containing questions, must be accompanied by the name and address of the writer, not necessarily for publication, but as evidence of good faith. No notice whatever will be taken of anonymous communications.*

"THE ELECTRICIAN" *is published every Friday morning, in time for the morning mails.* "THE ELECTRICIAN" *is on sale at the railway bookstalls throughout the Kingdom on Friday morning, and can be obtained of all Booksellers and Newsvendors; or direct from the Publishing Offices.*

New Volumes of "THE ELECTRICIAN" *commence in May and November. Old Back Numbers and Volumes of* "THE ELECTRICIAN" *are frequently wanted, and offers will be made by the Publisher therefor.*

Subscription Rates.—The rates for Subscriptions to "THE ELECTRICIAN" are as follows :—

	3 months.	6 months.	12 months.
	s. d.	s. d.	s. d.

THE ELECTRIC FURNACE.

In the Forest of Dean, the Romans, following no doubt the practice of the British iron-workers, built conical furnaces, and set them on the hill-tops to catch the wind. Probably one of the first improvements was to supply an artificial blast, and, but for the hot blast, which may be called a modification rather than an improvement, no essential change has since then been made in the commercial method of reducing ores. The oxyhydrogen blowpipe was an obvious improvement on an atmospheric blast, seeing that the nitrogen was worse than useless. DEVILLE and DEBRAY, using a lime furnace, both to retain the heat and to absorb the more fusible and volatile impurities, achieved the true smelting of platinum and aluminium. But here, for many years, metallurgical progress stopped. No higher temperature was known, and the rarer metals were reduced and fused with extreme difficulty.

The electric furnace may be said to have been discovered with the electric arc, and in the hollow crater of a reversed arc lamp, minature metallurgical experiments may be easily conducted. The most notable result of the commercial use of the electric furnace has been the production of aluminium in considerable quantities; and, quite recently, M. MOISSAN has produced uranium, chromium, and manganese. M. MOISSAN's experiments, a brief account of which will be found in another column, add one more testimony to the immense value of the electric furnace as an instrument of research. The possibility of reducing the most refractory metals, not in fractions of a gramme but in quantities amounting to many grammes at a time, cannot but materially aid the examination of some of those which are only imperfectly known. It is perhaps to be regretted that the affinity of uranium for carbon should be so marked at this high temperature that the winning of the pure metal is far from

Hosted by Google

easy; but it is probable that a re-treatment of the carbide with an oxide of uranium would eliminate the carbon, in a manner analogous to that in which the same element can be removed from iron when it is required to prepare the latter in a state of purity. Manganese might have been expected to form a carbide under the conditions prevailing during its reduction, not only on account of its similarity to iron, but also because it is known to be associated with large quantities of carbon in spiegeleisen and ferro-manganese. Seeing that the diamond form of carbon has been obtained by suddenly cooling under pressure a solution of carbon in iron, it would be interesting to ascertain whether a similar result would occur when manganese is substituted for iron. There is no reason why cobalt, palladium, iridium, and other useful, but not easily fusible, metals should not be produced at reasonable prices.

The history of aluminium during the last few years has shown that ingenious processes by which this metal might be made at a cheap rate are of little use, if a demand cannot be stimulated. This metal has been surrounded with a remarkable glamour ever since it attracted the attention of NAPOLEON III. In 1860 aluminium fetched £18. 10s. per lb.; in 1887 about £1 per lb. In 1889 it was offered by the half-ton at Pittsburgh at two dollars per lb., and in 1891, as the production of the Hall process, it was sold at one dollar per lb. Early in 1892 the price at Neuhausen was said to be 2s. 3d. per lb., and in May of last year 7½d. per lb. was talked of in America. In June, the price at Neuhausen was 2s. 6d. But not only is aluminium still a curiosity, but the lowest quotation elicited by some enquiries last week was 5s. per lb. for sheet, and we are inclined to doubt whether any real business has ever been done at 3s., excluding, of course, transfer between agents or associated companies. For most purposes, the bulk and strength is wanted rather than the weight, and allowing for its specific gravity aluminium at 4s. 8d. per lb. would be equivalent to sheet brass at 1s. 6d. The chemical process of reduction by the use of sodium yielded a very pure quality, but it was found that the alloys made in the Cowles' furnace were sufficiently useful, and as other electrical furnaces produce aluminium of 97 per cent. purity, there is no room whatever in commerce for the chemically pure metal. Platinum, as originally made by WOLLASTON'S process from chemically prepared spongy platinum carefully welded and forged into the solid, was of considerable purity, but platinum produced by an electric furnace by a smelting method contains several rare and refractory metals, notably iridium. The presence of iridium is useful, both in the manufacture of crucibles and in wire for electrical purposes, and is not, as many people suppose, added to platinum as zinc is added to copper in making brass. The electric furnace, whether used merely for the purpose of obtaining a very high temperature, as in the COWLES and MOISSAN patterns, or whether introducing at the same time electrolytic action, is likely to yield important results. The many uses found for tungsten-steel, nickel-steel, manganese-steel, chrome-steel, silicium-bronze, aluminium-iron or mitis metal, manganin, and other very useful alloys, depending, in many cases, on the presence of a very small proportion of a rare metal, offer encouragement for the discovery of new mixtures, even if the production of rare metals in their pure state is not as yet warranted by any known qualities and properties. So little, however, is known about metallic chromium, that the news of its successful reduction in the electric furnace, and of the ease with which it forms a carbide akin to those of uranium and manganese, were best received in grateful and respectful silence, qualified by a definite tendency to "ask for more."

SPARKING AT COMMUTATORS.

BY F. M. WEYMOUTH.

(*Continued from page 324.*)

Lastly, we arrive at the fifth in our order, the plane of maximum and minimum potential through the armature. This applies to the armature as the fourth applies to the commutator. It is indicated by the letters *M M* in the diagrams. When the brushes are at the non-sparking points on the commutator, this plane would come just slightly behind the plane of commutation, and consequently still further behind the plane of requisite reversal, as shown in Figs. 10 and 12. As with the second and third planes, so the coincidence of this fifth plane with the fourth is a pure matter of construction, and would, in fact, take place when the second and third coincided, as in Fig. 8. In Fig. 12 they will be seen to be at right angles with each other, similarly to the planes of non-sparking and requisite reversal. Though what we have termed a normally fixed plane, yet this and our second, third, and fourth planes may all be in some degree affected by moving the brushes, in so far as such movement may disturb the ratio of the strength of the self-excitation of the armature to that of the field. But this would only be, so to speak, an indirect effect, as compared with the directness of the effect on the plane of commutation caused by shifting the brushes.

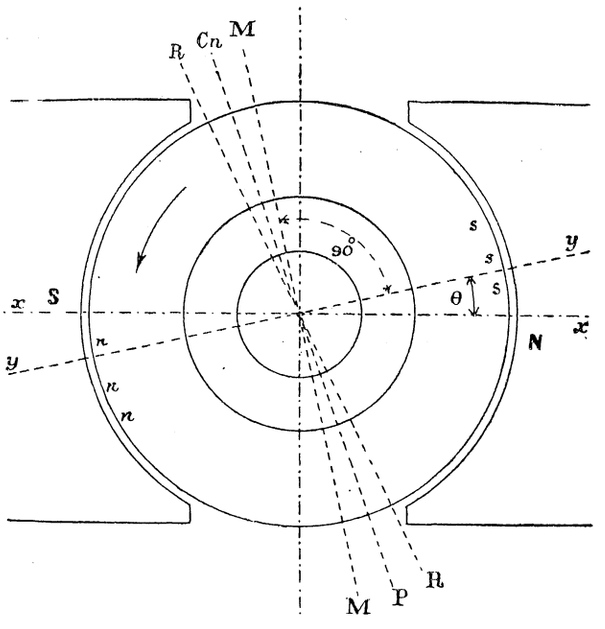

FIG. 10.—Armature Planes.

This last, or fifth, plane, however, we may here define somewhat more closely. For it may be understood to be that plane through the armature in which, when the coils arrive in it, they cease to *generate* the main current. It is the plane wherein, on the positive side of the armature, and supposing this to be symmetrically wound, as is usual, the currents from either half of the winding will meet, and, so to speak, form a "head;" though it might be more correct to say that it is the two electromotive forces from either side that so meet, except that the latter are not added together as are the two currents. When carried beyond this plane, the coils commence generating the reverse current. It is the plane which is normal, or at right angles, to the lines of magnetic induction traversing the armature core; and thus is the plane wherein the coils are neither excluding nor including lines of magnetism, and so cannot generate any electromotive force. This plane, moreover, is that which, perhaps, may be said to be the most important. For being itself directly governed by the field, it exercises control, as it were, over all the other planes. Having its position necessarily at right angles to the lines of magnetic induction running through the core, if these latter alter their angle with the horizontal, then this plane must follow suit. This is

Hosted by Google

made clear in the diagrams, Figs. 10*, 11*, and 12*, where the line $y\,y$ indicates the centre or mean plane of the lines traversing the armature, forming an angle θ with the horizontal centre line of the field $x\,x$. By the angle θ is thus represented what is known as the "distortion of the field"; and the more powerful the field in proportion to the self-magnetisation of the armature, the smaller will be this angle, and *vice versâ*. Hence, any

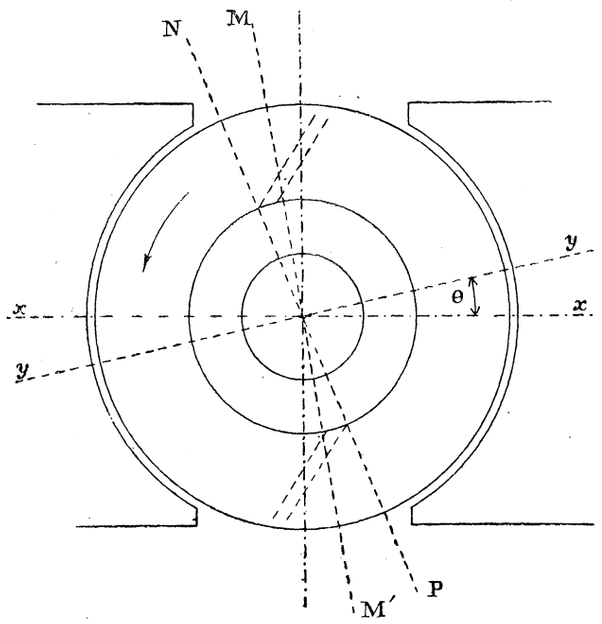

FIG. 11.—Commutator Planes. Brushes above and below.

cause affecting the angle θ will immediately produce a displacement of the plane M M, which in turn will also affect all the other planes. A dissertation on the self-excitation or polarisation of the armature, more especially in connection with drum winding, and the generation of current and potential, may be found in another article. (*See The Electrician*, Vol. XXIII., p. 273).

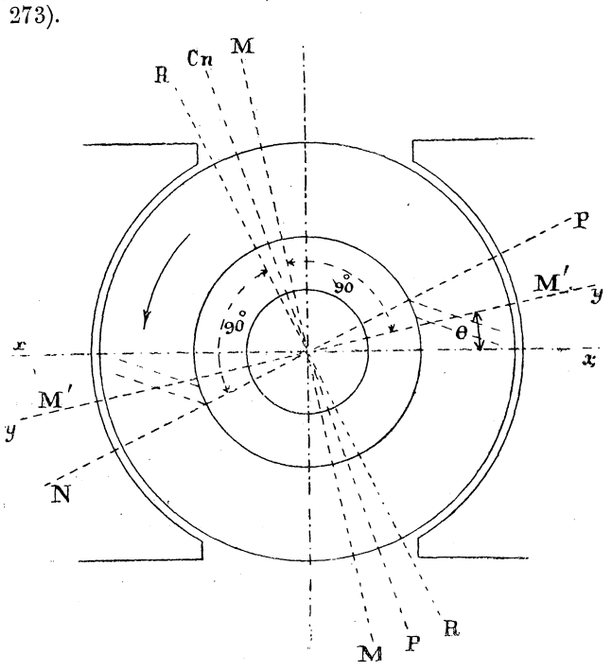

FIG. 12.—Armature and Commutator Planes. Brushes at the sides.

Having thus distinguished between the various planes, we may now turn our attention to Fig. 13. As may be perceived, this represents the top of a commutator, three of whose segments are lettered respectively r, s, and t; the armature coils

* Reproduced from *The Electrician*, January 20, 1893.

are represented between c and d, two of them being lettered b and f; and three of the lugs are lettered g, h, and i. The neutral plane of the commutator is assumed coincident with the plane of requisite reversal of the armature, and these are jointly indicated by the line R R. The point of the brush being just on this line, no sparking takes place. Two of the coils, b and f, are short circuited by the brush, and so are shown thicker; and the short circuits through the brush point are indicated by thick dotted lines. While the large

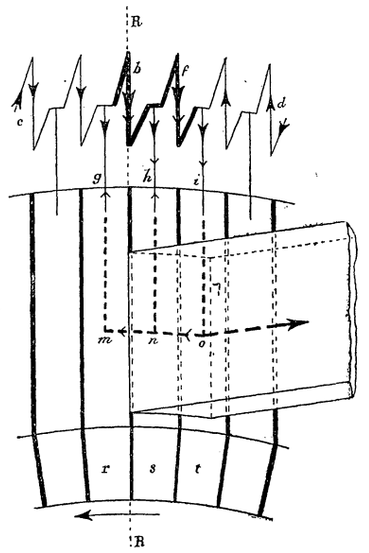

FIG. 13.—Non-Sparking Position. Short-Circuited Coil b in Plane of Requisite Reversal.

arrowheads show the main current arriving from the two halves of the armature winding, c and d, the small arrowheads represent the short circuit currents. It will be noted that the b and f coils have just left the series d, and are passing into the series c. Having passed the M M plane, the d current that was circulating within them, has first been stopped as they each arrived into the plane of commutation, and then a reverse short circuit current has been set up within them by the c electro-motive force. At the moment shown, this short circuit, or as for brevity we may term it, the $s.\,c.$ current, in coil b, exactly equals the c current. Meeting each other in the lug g, these two currents neutralise each other: hence there is no current flowing either way between the brush and the receding segment r. There thus being no current to break at the recession, there is no sparking. The positive brush being

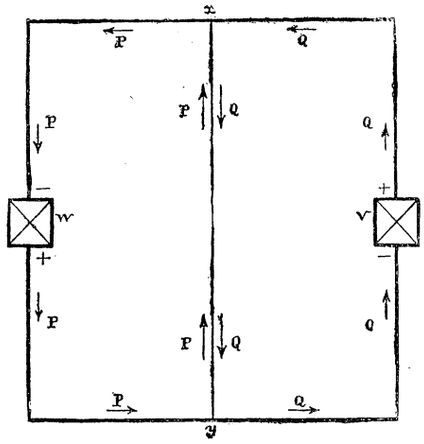

FIG. 14.—Two Circuits with Currents opposed in Common Conductor.

here shown, for the negative brush it is simply necessary to reverse all the arrowheads.

Now, in the above diagram there are *two* short circuits, namely, $g\,b\,h\,n\,m$ and $h\,f\,i\,o\,n$. In this connection we may turn to Fig. 14. We here find two circuits, P P and Q Q,

Hosted by Google

having a common conductor, $x y$. The generators are represented at w and v; and it will be seen that the currents oppose each other in $x y$. If the two currents are equal there will be no current in $x y$; while if they are unequal $x y$ will carry the difference. This, in fact, illustrates the essence of what is termed the "three-wire system," $x y$ representing the "neutral" main. It will be noted further that the P current leaving w, and the Q current leaving v, checking each other in $x y$, they each continue in the other's circuit. More accurately, it may now be said that there is only *one* circuit with the two generators in series; and, in fact, the two currents may be said to be *assimilated*. None the less, if the Q current be, say, 250 amperes, and the P current, say, 200, the Q current will split at x, 50 passing down to y and 200 only continuing by w. Uniting at y, 250 will enter the negative at v. Thus, though *assimilated*, the two currents taken separately retain their original values. Reverting to Fig. 13, we find that the two short circuits have in like manner a common conductor, $h n$, which will carry the difference between the currents generated respectively by b and f; for the latter will not be generating so large a current as the former.

We may now consider cases where sparking takes place. The most simple cases will be when the brushes are shifted too far forward or backward; or, again, which amounts to the same thing, if the brushes be at their right places, a cause of

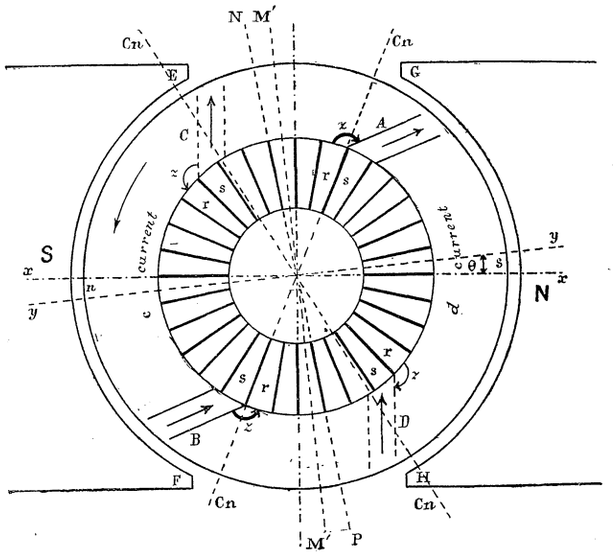

FIG. 15.—Diagram showing Brushes with too much Positive or Negative Lead.

sparking may be the oscillation of the neutral plane. This latter, however, trenches on ground which we cannot now enter upon, so we confine our remarks to the simple displacement of the brushes.

Fig. 15 herewith shows an armature revolving in a field, and a commutator, together with brushes. These latter are shown in positions A and B too far back, and at C and D too far forward. We now propose to deal with these four positions in detail, and consider the nature of the sparking that occurs in each one. Fig. 16 thus shows the brush at A (in Fig. 15). It must here be remarked that in these four diagrams, for the better elucidation of our subject, we have assumed a current output of 400 amperes, as shown on the brushes. Further, the conditions represented are *those that are broken* by, and so are *not* the results of, the recession of the segments r from the brushes. Short circuit (or s.-c.) currents of 500 and 450 amperes are assumed in the coils b and f, according as the one or the other is in the better position for generating E.M.F. The main armature currents c and d, of 200 amperes each, are indicated by the large arrowheads, and the s.-c. currents by the small arrowheads, as before. The double arrowheads represent *resultant* currents, whether by difference or addition.

It will now be seen, on reference to Figs. 15 and 16, that the brush A being on the d side of the commutator, up to the moment of the recession of segment r, there has been nothing whatever to reverse the current and polarity of the coils b and f. Hence their s.-c. currents will circulate in the same direction as the d current. As indicated by the large arrowheads, the latter still flows in these coils; though this is to anticipate. The two s.-c. currents, as explained in connection with Fig. 14, will become assimilated with each other, their difference only, 50 amperes, entering by lug h; and there will be a *normal* outflow of 500 s.-c. amperes through lug i, and a *normal* inflow of 450 s.-c. amperes by lug g. But now to consider the d and c main currents, we may take the former first. This would naturally attempt an inflow through lug i. It is, however, met there by the normal f s.-c. 500 outflow. The resultant 300 outflow is thus what remains. In this and the following diagrams it will be observed that the two amounts, which together produce a resultant, are struck out by a line drawn through. But the *whole* f s.-c. 500 is reduced by this same act. The 200 d, blocked back in i, takes the place of the missing 200 in f, or, in other words, becomes *assimilated* in that coil; and the b and f s.-c. currents being already assimilated, it becomes assimilated with both these currents. Now to consider the c main current, we find this inflows through lug g in the same direction as the b current. These thus *augment* each other, forming a united or resultant current of 650 amperes. To analyse this amount accurately, we observe that it is composed

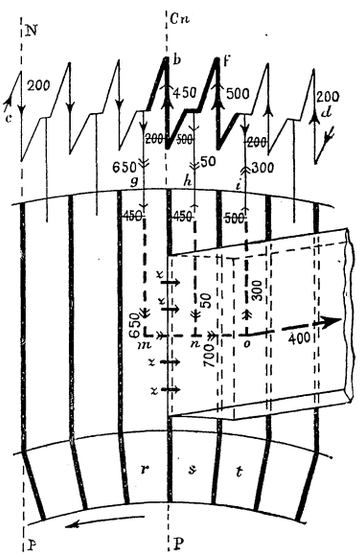

FIG. 16.—Positive Brush too far back. Heavy Forward Sparking. (Position A in Fig. 15.)

of 200 c + 200 assimilated d + 250 assimilated s.-c. currents; for, as pointed out, the d current is assimilated with the s.-c. currents. At the point n this amount is further augmented by the inflowing 50 down h, thus making a total of 700 from n to o. Of this total 400 goes up the brush, being the sum of the c and d currents, while the remaining 300 forms the 300 s.-c. current in lug i. We thus find the cycle of events completed.

Now, from the above we note that the actual current that is broken is *more than* the main output, being 650 amperes instead of only the normal 400. Furthermore, we observe that the spark which will occur at the recession will be due to the self-induction of both the c and d series of coils *plus* the additional effect produced by the short circuits, that is, to the self-induction of the whole of the armature-winding. Hence the sparking will be heavy, and will be in the same direction as the main current, as indicated by the thick arrows $z z$. A large current, moreover, being broken, there will be considerable burning with the arcs, especially of the segment r, which is here the positive electrode.

(*To be continued.*)

A Large Accumulator Order.—The Brussels Municipality is said to be contemplating the purchase of £20,000 worth of accumulators; £4,000 worth have already been ordered.

ON TESTING AND WORKING ALTERNATORS.*

BY W. M. MORDEY.

In connection with the testing of large dynamos, the provision of the necessary power is often a very serious matter; and the driving plant for this purpose is a heavy item in the equipment of a dynamo factory, especially as, in order to get the full output from machines of sizes that are now often made, much larger boilers and engines are required than for the works where the machines are made. Very little has been written about the actual testing of alternators, and, so far as I am aware, they have always been tested in the manner commonly followed with direct-current dynamos—that is to say, they have been run on circuits of lamps, or on wire or other resistances, either directly or through transformers. Where it is desired to test the prime motor as well as the alternator there is no need to do more than this; but when engine and boiler powerful enough are not available, or when it is desired to carry out long runs at the least cost in plant and fuel, other methods have to be sought for, and we naturally turn for assistance in this matter to the method of circulating power first devised and described by Dr. Hopkinson. It may be of interest to first glance briefly over the subject of testing by this method.

In Dr. Hopkinson's tests, published in 1886,† two similar dynamos were mechanically and electrically coupled. One ran as a generator supplying current to the other, which then acted as a motor and helped to drive the generator. It was necessary that the coupled machines should be driven by some source of power sufficient to provide for their internal losses. It was further necessary, in order that the circulation should take place, that one machine should have a higher E.M.F. than the other. When similar machines were used, this was readily arranged by weakening the field of the motor. Dr. Hopkinson introduced this arrangement with the special object of attaining a high degree of accuracy in determining the efficiency of dynamos. It is comparatively easy to obtain accuracy in measuring the electrical output or input of generator or motor. To measure the input or output of power mechanically is more difficult. Dr. Hopkinson reduced this difficulty by reducing the power required to be measured mechanically to less than one-tenth of what it would be under ordinary circulation. Lord Rayleigh‡ proposed to supply power to the coupled dynamos by an accumulator or small dynamo instead of by a belt, thus making the method completely electrical.

This method, in one form or another, has been frequently used for testing the efficiency of direct-current dynamos. When two similar dynamos are available it is very useful, although the positive coupling is rather a drawback. If a belt is used, then the loss in the belt is included in the power required to be furnished to the combination. By running with and without belt or other gearing we have a simple way of finding belt or gearing losses—a matter that is involved in some obscurity. For this, as for other purposes, the method has the advantage that the losses in the mechanical transmission of large powers may be tested without the absorption or generation of large power.

But quite apart from the testing of efficiency this method has a good quality of a very solid kind, as it enables large dynamos to be run at full load by small engines. To the manufacturer this is often of great importance. It is necessary or advisable to run machines at or over their full load for a sufficient time to ascertain their mechanical qualities and how much they heat, and so on. And on the principle of Dr. Hopkinson's method small engines may be used, as it is only necessary to circulate the power by placing motors or resistances on the dynamo circuit instead of lamps, and causing these motors to drive back on the engine, countershaft, or dynamo. The engine then has to supply only power sufficient to cover the conversion and transmission losses. I do not think advantage is taken of this as often as it should be.

In the case of dynamotors or of high and low-pressure machines, the method may be applied by coupling the armatures together, high pressure to high pressure, and low pressure to low pressure, and supplying only power to cover the losses. In some cases large direct-current dynamos have been made with two armature windings and two commutators. It will be seen that a complete test may be taken with a single machine of this kind by circulating the power within the machine, adding an E.M.F. sufficient to enable the generator half to force the full current against the E.M.F. of the motor half. The power so added gives the internal losses, and the efficiency is, of course, readily ascertained. A single dynamotor cannot be tested in this way, as the two windings are usually very dissimilar.

So far as I know, the first application of Dr. Hopkinson's method to alternate-current work was by Dr. Sumpner,§ who, some months ago, worked out and published a very interesting plan for testing transformers in pairs by circulating the power. When it is remembered that the full-load efficiency of transformers is something like 96 or 97 per cent., it will not be necessary that I should dwell on the economy of this plan.

Dr. Hopkinson's method may be applied to two alternators coupled mechanically and driven as in his original test of direct-current dynamos. It is, however, much more convenient to be able to run machines singly. The necessary conditions for this are readily realised in an alternator, especially if the armature is stationary; and in this way I wish to show, in the first place, that it is possible to run an alternator under all the essential conditions of full load with only a small absorption of power. This may be done simply by dividing the armature circuit into two portions,

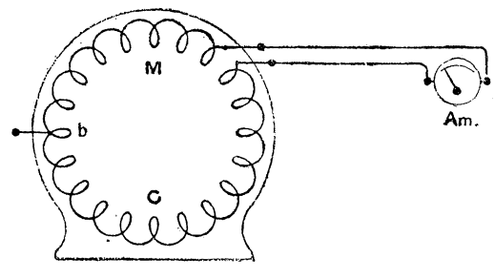

FIG. 1.

and so connecting them together that one has a higher E.M.F. than the other, the stronger portion acting as a generator, absorbing power, and driving the current through the weaker portion, which acts as a motor, returning the power to the generator portion, less the losses. The two portions of the armature may be made of unequal E.M.F. by dividing the armature into unequal portions, as shown by Fig. 1, which represents the armature of an alternator. The coils are joined up so that the portion M is opposed to the portion G. By making G greater than M, and by running with the field magnet excited, any required current may be made to circulate round the whole armature. This current is measured by an ammeter put in at any part of the circuit. The volts of each coil, or the volts across the junction of the portions M and G, may be taken in the usual way. When the full current is circulating, with the full field and full speed, the machine will be working at full load, so far as mechanical strains and electrical losses are concerned, and the power to drive it will be merely that required to make up for the mechanical and electrical losses. The efficiency is then simply found.

Test of an "A 20" 250-Kilowatt Alternator.

The machine was driven by an engine from which indicator diagrams were obtained. It was found that the indicated kilowatts were 3 kilowatts more when excited than when not excited. This is lost in eddies. The armature was then joined up in two portions, as in Fig. 1, and a current of 60·25 amperes circulated, with a potential difference of 1,656 volts across the junction of the two.

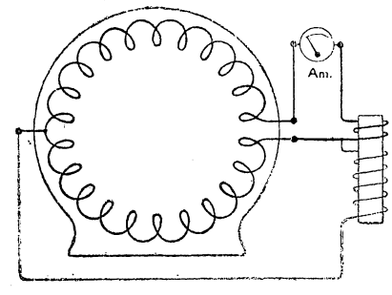

FIG. 2.

This was equivalent, so far as internal losses were concerned, to an output of $1656 \times 60{\cdot}25 \times 2 = 199{\cdot}5$ kilowatts. The power absorbed was 6·37 kilowatts more than when not excited. As the power wasted in eddies was 3 kilowatts, the loss due to the circulation of the current is $6{\cdot}37 - 3 = 3{\cdot}37$ kilowatts. To check this, we may examine the resistance. The armature has a resistance of 0·23 ohms when the two sides are parallel, but as all the coils were in series in this test, the resistance was $0{\cdot}23 \times 4 = 0{\cdot}92$ ohms. We will call this 1 ohm to allow for a slight increase due to heating. The C^2R loss thus would be $60{\cdot}25^2 = 3{\cdot}63$ kilowatts. This is a very fair confirmation. As a matter of opinion, I have very little doubt that the eddies are less under load than on open circuit.

To ascertain the efficiency we have to add the excitation and the friction. The excitation was 1·365 kilowatts. The friction is the

only quantity not determined, as it could only be obtained as part of the total friction, including engines, ropes, and alternator. But I have put down 3 kilowatts for alternator friction, and this will no doubt be considered fair, as there was scarcely any perceptible warming of the bearings. A good deal of air is moved by the magnet, but we know that in this very little power is spent. The losses are :—

	H.P.	K.W.
Friction	4	3
Excitation	1·83	1·365
C^2 R and eddies	8·54	6·37
Total	14·37	10·735
Output	267·47	199·5

Commercial efficiency—

$$\frac{199\cdot5}{199\cdot5+10\cdot735}=0\cdot9489.$$

The "electrical efficiency"

$$=\frac{3\cdot63+1\cdot365}{199\cdot5+3\cdot63+1\cdot365}=0\cdot9675.$$

In the above I have expressed power in kilowatts instead of horse-power, not merely out of deference to the President, but because almost all the quantities are actually determined and required to be known in kilowatts, and because I think it the most simple and convenient way.

Another way to upset the balance between the two portions of the armature is shown by Fig. 2. The secondary of a transformer is interposed in the armature circuit, the primary of this transformer being connected across the junction of the two portions, or wherever convenient. The two portions of the armature have equal and opposite E.M.F.'s and the transformer secondary provides the E.M.F. necessary to cause the circulation. It is only necessary, as in the first case, to run the machine with a full field to produce in it all the conditions of full load. I have only tried this plan to see that it works, but have not used it for any actual tests. The unbalancing E.M.F. may of course be supplied by another alternator instead of by the machine under test.

In these methods of running and of testing, the power required to drive the alternator has to be supplied and measured mechanically. This may be done by a transmission dynamometer, or by indicator diagrams of the engine. Neither of these methods is quite satisfactory, or quite direct enough. Transmission dynamometers are not always at hand, and, when available, a good deal of careful preliminary work is needed to get accurate results. Indicator diagrams are not very satisfactory. The power which is required to be known may be only a small part of that actually developed, and, especially with large engines running on light load, diagrams are not easily read with any high degree of accuracy. A better plan would be to use an electromoter to drive the alternator, especially if directly coupled so as to avoid the use of belts. The power supplied to the motor may be measured electrically, and the necessary deduction made for the motor.

A direct electrical measurement of the whole of the losses is, however, the only one that can be considered fully satisfactory. One way in which this may be obtained is shown by Fig. 3. This arrangement reduces the power necessary to test a machine at full load to rather more than half the usual amount.

An alternator armature, A′, is divided into two portions, M and G. The machine is run up to synchronism with another alternator, A, which may be of about half the capacity of the machine to be tested. The part M of the machine A′ is then run as a motor, while the part G is used as a generator doing work on an external circuit, R. The belt is thrown off. The machine acts, in short, exactly in the manner of an ordinary direct-current dynamotor. The input and output are measured by wattmeters or otherwise across the respective terminals.

The total losses = input + excitation − output.

The efficiency as a dynamotor $=\dfrac{\text{output}}{\text{input}+\text{excitation}}$.

When the generator portion is working at half the normal output of the alternator, the motor half will be working at a little more than its full load, and the internal losses will be the same as if the machine were working at full output (the only difference being that the friction losses are put in electrically instead of mechanically). The full-load efficiency under these circumstances

$$=\frac{\text{output}\times 2}{\text{input}+\text{output}+\text{excitation}}.$$

It will be noticed that this involves the assumption that the efficiency of the machine as a motor is the same as when used as a generator—an assumption that is fair.

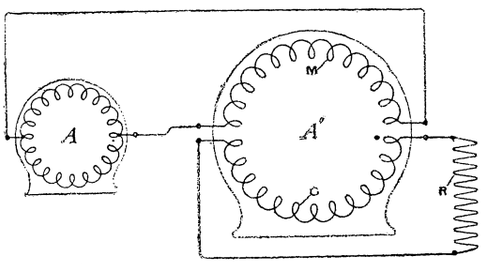

Fig. 3.

Some particulars of a test of an "A 10" 50-kilowatt alternator arranged in the manner shown in Fig. 3 are given below. The machine was separately excited and driven up to synchronism with a 25-kilowatt alternator. One half, M, of the armature was then run as a motor, and readings were taken of the current, volts and watts—the latter by a modified Siemens electro-dynamometer, used as described by Dr. Fleming, and having an added resistance of 1,000 ohms of non-inductive platiniod wire capable of easily carrying a current of 2 amperes. The generator portion, G, was run on a circuit of straight platiniod wire, and the output was measured in amperes and volts. The circuit was one that had been in use for a long time, and had been carefully tested and found to be non-inductive and without sensible capacity. The test of this circuit, as of others in which a similar quality was desired, consisted simply in ascertaining that a given potential difference, whether alternate current or continuous current, gave similar current readings on a Siemens dynamometer. True watts are therefore correctly given by $C'\times V'$. The field was separately excited, and the current and volts measured. Speed was constant at 600 revolutions, = 100 ∿.

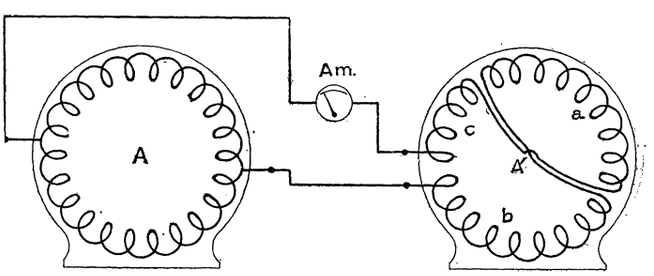

Fig. 4.

Another way, arising naturally out of Fig. 3, is to circulate the power given by the portion G back to the circuit of A to M instead of wasting it on the resistance R. This may be done by putting one winding of a transformer of suitable size in place of the resistance R, and a second winding of the transformer in the circuit between A and M. In order that this should succeed it is necessary that the transformer should be capable of allowing a sufficient current to pass through one winding alone to run the machine as a motor lightly loaded. Then the portion M will be traversed by a current larger than that produced by G, otherwise the machine would not run as a motor.

Another way, which has the advantage of being a complete electrical method, is shown by Fig. 4. The armature, A′, of the alternator to be tested is divided into, say, three portions—*a*, *b*, and *c*—which are so joined up that the portions *a* and *b* neutralise one another so far as E.M.F. and power are concerned. Then the machine is run up to synchronism with the generator A, which is made to supply current to A′, and the belt is thrown off. It will be evident that A′ runs as a motor purely by virtue of the power of the portion *c*. The portions *a* and *b* do nothing. If the field of A′ is suitably excited, and the portion *c* is correctly proportioned, the full working current may be forced through the whole armature, and all the internal conditions of full load will be observed, with the exception that the torque will not be in the same sense all round the armature—a matter that does not interfere with the accuracy and value of the test. A single wattmeter reading taken at the terminals will then give the whole of the power expended in the machine, including mechanical and electrical friction and eddies, as well as excitation if the exciter is directly driven.

Other ways of driving the alternator electrically, and of testing it under the conditions of full load, will readily suggest themselves. For instance, a portion of the armature may be separated from the remainder and supplied with power from an external synchronous source sufficient to run the whole machine, and the portion not so used may be used, as in Fig. 1 or Fig. 2, to circulate power within the machine. In such an arrangement, however, the different portions of the armature are not equally loaded. Running at full current and small power may also be done by using simple choking

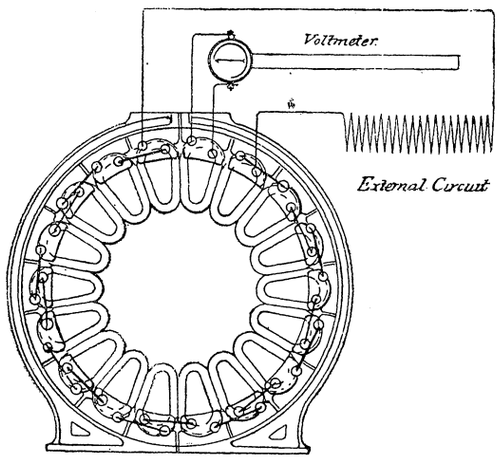

FIG. 5.

coils for the external circuit, but this introduces disturbing influences which make it of very little use. Another way of testing alternators economically may be mentioned. Two years ago* I described an experiment made with one of my alternators, showing that if one coil of the armature is left out of circuit (as shown in Fig. 5), the E.M.F. of that coil remains constant whatever load may be imposed on other portions of the armature, so long as the speed and excitation remain constant. I found also that the true load characteristic for the whole armature might be taken by loading one coil only. This being the case, it follows that an alternator may be fully tested by an engine or motor capable of running only a very small portion of its load. Such a test, although giving all needed electrical information, does not cover the practical considerations that render advisable the long-continued running under the conditions of full load. But it may sometimes prove to be useful. It follows from this that if a portion of the armature be used as a motor, another portion may be loaded as a generator and the full-load characteristic of the machine obtained, while another portion may be run on a voltmeter only and the open-circuit characteristic ascertained. I will not occupy further time by alluding to other modifications of this kind. Those I have described suffice to show how useful results may be obtained.

(To be continued.)

Compound Telephone Wires.—A new kind of telephone wire is being experimented with in Germany, consisting of an aluminium-bronze core with a copper-bronze envelope. It is said to have a low resistance and to have great tensile strength.

THE ROTATING ELECTRIC FIELD AND THE ROTATIONS DUE TO ELECTROSTATIC HYSTERESIS.*

BY RICCARDO ARNÓ.

In his well-known researches on "The Electrodynamic Rotations produced by Alternating Currents,"† Prof. Galileo Ferraris demonstrated that by means of two simple alternating currents flowing in fixed coils a rotating magnetic field could be generated, and by means of the resultant induction phenomena, Arago's historic and classic experiment, the rotation of a copper cylinder placed within a magnetic field could be obtained. Moreover, in one of his fundamental experiments Prof. Ferraris showed that an iron cylinder rotates in a rotary magnetic field, even when it is cut in such a way that no Foucault currents are produced. In this case he remarked that the rotation was due to magnetic hysteresis, viz., to the lagging of the magnetisation of the iron behind the rotation of the magnetic field.

My experiments‡, following this line of thought, show that when electric forces are substituted for magnetic forces, and magnetic bodies are replaced by dielectric bodies, phenomena similar to those observed in the case of the cut iron cylinder occur. Even before Mr. Steinmetz's§ experiments on the simple fact that in the dielectric of a condenser, inserted in the circuit of an alternating electromotive force, a consumption of energy takes place which shows itself by the heating of the dielectric, it was already evident that in a dielectric medium under the influence of an alternating electrostatic field electrostatic hysteresis took place, as did magnetic hysteresis, in magnet bodies placed in an alternating magnetic field. It was then easy to predict that a phenomenon similar to the rotation of a cut cylinder of some magnetic material would be obtained with a cylinder of some insulating material placed in a rotating electric field. In this case, also, the rotation of the cylinder should be caused by the lag of the polarisation of the dielectric body behind the rotation of the electric field to which it is due. It was, therefore, natural that, in order to experimentally verify these predictions, I should have recourse to arrangements similar to those used by Prof. Ferraris in his experiments on electro-dynamic rotations. In fact, if at a point O (Fig. 1),

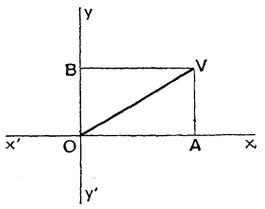

FIG. 1.

instead of two magnetic fields, as in Ferraris' case, two *electric* fields are superimposed in the directions O*x* and O*y*, they will also cause a resultant electric field, whose intensity O V is obtained by composing, as if they were two forces, the intensities O A, O B of the two electric fields, provided, however, that the space occupied by the two fields be filled with a substance whose dielectric constant has the same value at every point. If, moreover, the two electric fields vary according to the sine law, have the same period and a difference of phase, then the point V describes an ellipsis with a centre O, which is reduced to a circle if the amplitudes of the two component fields are equal, and, the directions of the two fields being normal if the angular value of the phase difference amounts to 90deg. In this particular case the resultant electric field has a constant intensity, and its direction revolves with uniform velocity. In the same that the two magnetic fields intended to generate a rotary magnetic field can be obtained by means of two alternating currents traversing two fixed crossed coils, the two electric fields required to produce a rotary electric field can be obtained by means of two alternating potential differences between two couples of fixed metallic crossed segments.

In order to obtain the two potential differences necessary for my experiment, without being obliged to have recourse to a dynamo or a polyphase electrostatic machine, I had recourse to an arrangement like one of those used by Prof. Ferraris in his classical experiments, in which it was necessary to derive from a single circuit the two alternating currents he required for the production of his rotary magnetic field. The arrangement consists in using

the currents in two branched circuits, in which equal apparent resistances are constituted, in one case by a great ohmic resistance, and the other by a great inductance. The same considerations which hold for two parallel circuits can, in fact, be made to hold for two series circuits; provided the differences of potential at the ends of these circuits be considered, instead of the currents as in the Ferraris method. While in Prof. Ferraris' experiment the main current divides itself into two currents, presenting necessary the difference of phase for the production of the rotary magnetic field, in mine the given difference of potential sub-divides itself in two differences of potential, which are also displaced in phase in the manner required for the generation of a rotary electric field It is needful, however, to remark at once that in this, as well as in the other cases, the required difference of phase can be obtained by means of condensers. Nay more, the employment of condensers, which, in the experiments on rotary magnetic fields is not without practical difficulties, turns out to be very convenient here, where it is a case of very high potentials and very feeble currents, and therefore but little electrostatic capacity is needed.

In Fig. 2 is shown the arrangement of circuits in my experiments. In M a Siemens' low voltage alternator is represented, r is a commercial rheostat, E Siemens' electro-dynamometer, V a Cardew voltmeter; P Q, R S respectively are the primary and secondary wires of a large Ruhmkorff coil deprived of its commutator, and used as a simple transformer intended to produce a considerable difference of potential between the two points R and S. In the secondary circuit are inserted a large ohmic inductionless resistance A B, a condenser C D, the electrostatic capacity of which may be very little. The four points A, B, C, D, are respectively put in communication with four slightly curved vertical copper segments, a, b, c, d, arranged as shown. A mercury commutator I reverses the connections of the two segments c and d, with the points C and D. A Thomson electrostatic voltmeter, not shown on the drawing, serves as a measure of the differences of potentials between A B, and C D. In Fig. 3 we have a perspective drawing of the

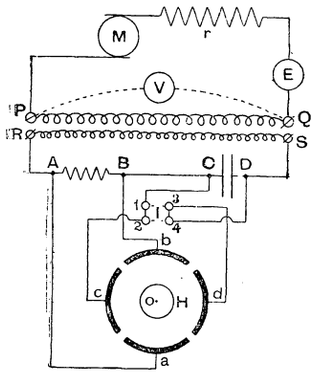

Fig. 2.

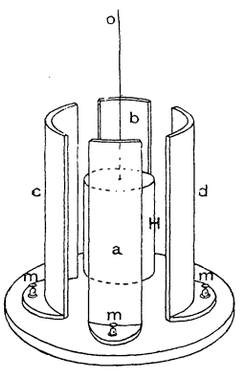

Fig. 3.

arrangement of the four segments a, b, c, d, enclosing the space in which the rotating electric field is to be produced. In order to make the figure clearer the segments are shown much narrower than they really are. The axis of the apparatus is shown at O, and the terminals by means of which the four segments are connected with the points A, B, C, D (Fig. 2) are shown at m.

Once things are thus arranged, it is easy to predict what was actually verified by experiment. In fact, let us consider the secondary circuit of the transformer, comprising the secondary wire R S of the same, the resistance A B and the condenser C D, and let us call i the current in the circuit, V_1 and V_2 respectively the potential differences between the ends of the resistance A B and between the plates of the condenser C D. We know that, while between the current i and the potential difference V_1 there is no difference of phase, the current i is ahead by one quarter of a period of the potential difference V_2. Then V_2 lags a quarter of a period behind V_1. A glance at Fig. 2 is then sufficient to enable us to foresee that the electric field generated by the two differences of potentials V_1 and V_2, in the space enclosed between the four segments a, b, c, d, must turn in the direction of the hands of a watch, when the commutator I is in the position 12, 34, shown in the drawing, and in the opposite direction when the connections of the segments c and d with the points C and D are reversed by means of this commutator. If, however, the resistance A B and the electrostatic capacity of the condenser C D are properly determined, so that, as may always be obtained by trial, the two differences of potential V_1 and V_2, and consequently the mean intensities of the two component electric fields, may be made equal, the resultant field has a constant intensity and revolves at a uniform speed.

In a first experiment I suspended a little hollow mica cylinder, H (Figs. 2 and 3), in the rotary electric field by means of a silk thread. As long as only one of the two pairs of segments, a b and c d, is in communication with the points A B or C D, the little cylinder remains motionless; but when both pairs of segments are respectively in communication with the points A B and C D, the little cylinder immediately begins to turn round its axis and in the direction of the arrow shown in Fig. 2, if the commutator I is in the position 12, 34, which is exactly as was foreseen. If, while the cylinder is spinning in such a direction, the position of the commutator I is reversed, the rotation rapidly ceases and begins in the opposite direction. The experiment was repeated with the same result when the little mica cylinder was replaced by little hollow cylinders of paraffined paper, glass, ebonite, wax, and other insulating substances.

In another experiment I devised a little electrostatic motor, working by means of alternating differences of potential. Fig. 4 is a section normal to the vertical axis of rotation O. The fixed part of the apparatus is constituted by four vertical copper segments, a, b, c, d, like those used in the previous experiments. They are separated, the one from the other, by means of four ebonite strips S, and fixed by screws to an ebonite disc Z. The copper segments and the ebonite strips together form a cylinder 20cm. in height, with an inside diameter of 10cm. The moveable part consists of a hollow closed ebonite cylinder H, which is moveable around its axis O, and supported on two steel points turning in glass holes. The cylinder weighs 40·33 grammes, is 18cm. long, and has an outside diameter of 8cm.

To put the above described little motor in action I arranged the experiment exactly as in Fig. 2, joining the terminals 1 and 1′ (Fig. 4) of the segments a and b with the points A and B, and the terminals 2 and 2′ of the segments c and d with the points C and D. The condenser C D was constituted by a wine-glass 1mm. thick, containing mercury and covered on the outside with tinfoil having a superficial area of about one square decimetre; its electrostatic capacity was therefore very small, about $3 \cdot 10^{-4}$ microfarad. In order to have the resistance A B, which must be very great, free from self-induction, I first had recourse to a little boxwood bar, sufficiently dried, in which, at different distances, little holes containing mercury had been sunk. Afterwards, with much better results, I had recourse to a column of distilled water, 3·5mm. in diameter, the length of which might be varied in order to obtain such conditions of current as would meet the requirements of the best working of the apparatus. The effective alternating current in the primary circuit was

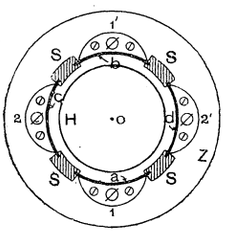

Fig. 4.

seven amperes, the frequency 40, and the effective volts of the primary coil were 27. The experiment showed that the little motor worked best when the effective difference of potential between the points A and B was equal to that between the points C and D. This difference of potential, measured on the Thomson electrostatic voltmeter, was 3,800 volts, and the column of water inserted between A and B, which had in that case a length of 54cm., had, at a temperature of 22·5°C, a resistance of 13·5 megohms. In these conditions the ebonite cylinder started itself and acquired after a few minutes a speed of about 250 revolutions a minute.

In other experiments I also arranged a condenser, made of one or more Leyden jars, in parallel with the secondary coil of the transformer. By so doing I was able to notably increase the difference of potentials between the ends of the resistance A B and between the plates of the condenser C D, so that the strength of the two electric fields was increased, and greater effects could be obtained.

At last, to have an idea of the order of magnitude of the moment of the couples of rotation, I suspended an ebonite cylinder, 139mm. long. and 61mm. outside diameter, in the electric field by a bifilar suspension. A little plane looking-glass attached to the cylinder served to make the angular movement visible. An approximate measure of this angle could also be had by means of an index and a graduated circle. This circle, fixed on the upper ends of the segments a, b, c, d, so as completely to cover the cylinder formed by them, had, at the same time, the effect of eliminating the disturbances produced by air currents. The weight sustained by the bifilar suspension was 23·053 grammes = 22,615 dynes. The distance between the two threads was 4·6 cm.; their length was 155cm.; the deflection 3° 17′. Therefore the moment of the couple was 176 centimetre^2 gramme/second^2.

The experiments can be used to show in an experimental way the phenomenon of electrostatic hysteresis in dielectric bodies, and to make evident the existence of the difference of phase which can be obtained from two alternating differences of potential of equal period. They offer, moreover, a means of quantitative research on electrostatic hysteresis, and on its influence in the case of various differences of potential and various dielectrics. With this idea in view I am continuing my investigation. Meanwhile I must express my best thanks to Prof. Galileo Ferraris, whose advice assisted me so greatly.

M. JANET'S EXPERIMENTS WITH HIGH-FREQUENCY CURRENTS.*

The interesting experiment of Elihu Thomson, which consists in lighting an incandescent lamp by shunting it with a few turns of copper (Fig. 1) traversed by a high-frequency current, is well known. At the exhibition of the Société de Physique, M. Janet

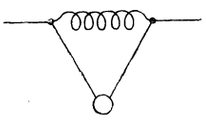

FIG. 1.

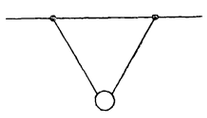

FIG. 2.

repeated this experiment with success, but replaced the spiral by a simple rod of copper (Fig. 2). The phenomenon appeared explicable, as in the case of Elihu Thomson's experiment, either by the self-induction of the rod, or by an actual increase in its resistance. M. Janet has, however, recently shown in a simple manner that the effect should be attributed to mutual induction. He brought one of the wires of the lamp circuit parallel to the principal circuit, as shown in Fig. 3, insulating it by a glass tube ; the lamp

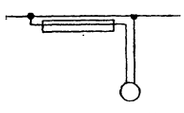

FIG. 3.

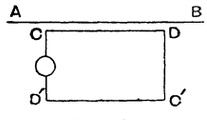

FIG. 4.

went out immediately. If a rectangular C D C' D' is brought up to the rod A B, a lamp in the circuit C D C' D' lights up (Fig. 4). If the circuits are arranged as in (Fig. 5) and a condenser is introduced into the circuit C D C' D', the lamp brightens up if the con-

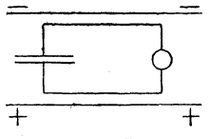

FIG. 5.

conditions are suitable. In fact, if we have a variable inductance in the circuit C D C' D', the capacity being fixed and the inferior to a certain value, the brilliancy of the lamp attains a clearly marked maximum for a certain value of the self-induction. This maximum occurs when the period of the secondary circuit is equal to that of the primary current. On the other hand, if the capacity of the primary circuit is altered, it is found that in order to obtain the maximum brilliancy either the capacity or the self-induction of the secondary circuit must be similarly altered. This circuit, therefore, reassumes for such frequencies its true *role* of resonator of which the experiments of MM. Sarassin and De la Rive have deprived it in the case of Hertzian oscillations. It may probably be concluded that in the case of frequencies such as those employed by Elihu Thomson damping out is much less rapid than for Hertzian oscillations.

THE THEORY OF DIELECTRICS.†

BY A. HESS.

The author presented some results which he had arrived at after an investigation of a particular case of Maxwell's theory of heterogeneous dielectrics.

A dielectric sheet may be compared to two condensers of different specific capacity and resistance arranged in series. Assuming that one of the condensers possesses an infinite resistance, and that the other possesses a certain conductivity, it is found that by charging this system by a constant electromotive force the difference of potential ε between the plates of the insulating condenser increases continuously, whilst the pressure ε' of the conducting condenser passes through a maximum, and finally tends to zero. The result is that the charging current falls but slowly. During discharge through a resistance the variations of the potential differences are reproduced in reverse manner, the conditions being the same ; ε' becomes negative, and passes through a minimum. The sum of the pressures $(\varepsilon+\varepsilon')$ falls very rapidly, so that the discharge current is almost extinguished, whilst in the interior of the system there still exist considerable but mutually equilibrating pressures. Whilst the condenser is insulated ε remains constant, but ε', which is negative, diminishes in absolute value according to the ordinary exponential law. Hence the important consequence that the total pressure increases during rest, and may then give rise to a residual discharge.

The ratio E/I (observed electromotive : charging current) at a given moment is often assumed to represent the insulation resistance. As a matter of fact, this ratio has nothing in common with the insulation resistance, it being infinite in the case under consideration. It has been observed that the insulation diminishes when the temperature rises. This fact is explained by the increase of the charge when the resistance of C', which generally behaves like an electrolyte, diminishes.

Again we represent a dielectric in a more complex manner by adding to the two condensers in cascade a third condenser in parallel. Heterogeneity does not involve a residual discharge where the products of the resistances into the capacities of the various condensers are equal. From this it can be seen that for every mixture of two dielectrics there is a temperature at which the phenomenon of the residual charge disappears.

M. Hess then described an experiment carried out to verify the accuracy of his calculations. He coupled two Carpentier condensers of 0·1 and 0·5 microfarad respectively in series, and shunted the latter by a 100 megohm resistance formed by a pencil mark on a sheet of roughened glass. He thus obtained a system which only charged very slowly, and which furnished after a first instantaneous discharge a large number of residual discharges.

The hydraulic analogue of a condenser was, the authors said, a U-tube, the two legs of which represented the plates, the level of the liquid corresponding to the potential. The author showed a device which rendered possible the production of phenomena analogous to those obtained with two condensers in series. The apparatus consisted of three branches, two of which communicated at the top by a narrow tube, acting as a conductor between the plates of one of the condensers. The system was charged by exerting pressure in one of the extreme branches. The instantaneous discharge corresponded to the instantaneous expulsion of the air when this branch was opened. On insulating the condenser, this branch was closed in the model; on again opening it, there was a fresh expulsion of air. In these various phases the levels of the liquid varied like the potentials in the system of condensers.

THE POSITION OF ALUMINUM.*

The great advance that has been made in the metallurgy of aluminum within the past ten years is one of the most hopeful signs of the application of scientific principles to commercial problems. When one recalls the status of this matter in 1880, when aluminum was but little more than a plaything, and an expensive one at that, and then refers to the present condition of the industry, he is impressed with two considerations. First, that so much has been done to cheapen the processes for the extraction of this metal from its ores, and, second, that in all probability the methods now in use will be discarded before 1900. A great deal of laborious and costly work has been done, and the result is that aluminum can be bought for 50 cents per pound as against $12 in 1886. This is indeed a great achievement, and one of which any man may well be proud. It is often quite as useful to point out the way in which a desired result is *not* to be reached as to show how it may be attained. It is in this direction that a great deal, if not most, of the work that has been done on the commercial extraction of aluminum is valuable. In spite of the wonderful cheapening of the product, in spite of the outlay of hundreds of thousands of dollars, in spite of the beautiful pictures that are held up to view of the future of this magical metal, what have we to show for it all ? So far as concerns the future of aluminum, it may said that unless it can be made in large quantities, just as lead or copper or zinc, it cannot hope to enter as an important factor in the great industries. It must be smelted in large quantities direct from its ores, or obtained as a bye-product in the preparation of some widely consumed substance, ere it will take in trade the position its qualities command.

† Abstract of a Paper read before the Société Française de Physique.

* From the *Engineering and Mining Journal* of February 4, 1893.

Hosted by Google

A great deal of nonsense has been written about aluminum, and a great deal of vital force expended in prophesying its brilliant influence upon civilisation. The truth is that the industry is but little beyond the experimental stage, and may be compared to the manufacture of iron in the days of Tubal-Cain. It is not likely that at the present time the greatest producer of aluminum is making regularly one ton per day, and the total daily output of the world is short of five tons per day, and this result has been reached after a quarter of a century of constant investigation, and at a cost of vast sums of money. It is, nevertheless, a result to be proud of, for it has brought into use, if not on a large commercial scale. at least on an important one, a valuable metal. But we do not think that the further prosecution of electrical methods, by which alone aluminum is now made, will bring the cost of it to the point at which it will become a prominent metal, *unless*, and we desire to lay especial stress on this, they proceed along the line of direct reduction. Even here it is by no means certain that they can make it cheap enough. Aluminum is cheap now compared to the prices of ten, or even five years ago, but the plea we make is that it is not cheap enough. One reason why the prominent metals are cheaper now than they have ever been is because of the immense output, and this in turn is conditioned by modern methods, the use of improved machinery, and better management.

Looking at the matter from a standpoint of practical results and the cost of them it would seem that there is too much reliance placed on electrical methods, whether electrolytic or electro-chemical. It may be urged that inasmuch as by means of electrical methods aluminum has been reduced in price from $12 to 50 cents per pound, and inasmuch as large investments have been made in such plants, it were better to attempt the solution of the problem in this way; that, in fact, more is to be expected from methods that have already done so much than from others that have accomplished nothing. And this is sound reasoning so far as it goes, but it does not go far enough. It proceeds on the assumption that electricity is capable of indefinite cheapening. There is a very inviting field for research here, and one that to the earnest metallurgist is as attractive as the refining of cast iron was to Kelly and Bessemer in the early fifties.

While we would not be understood as condemning the electrical reduction methods, we would encourage those who seek by other means to make cheaper aluminum. Those who have brought the present methods up to their known efficiency are probably best qualified to investigate possibilities that lie in other directions, for they know the commercial limitations affecting the employment of the current for large and regular products, and have the skill and energy and professional training that will be needed. Let us have cheaper aluminum, and after that, perhaps, still cheaper aluminum. Tubal-Cain's furnace did very well for his day and time, but would be now somewhat out of date, not because it could not make good metal, but because it could not make enough of it, or make it cheaply enough.

THE COST OF AN ALTERNATE-CURRENT SUPPLY.

The following figures, taken from the *Elektrotechnisches Echo* of January 7th, will be of interest, the details given being very full. They relate to the Cologne Central Station,* which is in the hands of the Municipality, and are for the half-year, October, 1891, March, 1892.

The station is about a mile and a quarter from the central point of the system, and contains two 400-kilowatt machines and one of 100 kilowatts, driven by horizontal condensing engines, running at 85 revolutions. The alternators have a pressure 2,000 volts at 50 ∿, and run in parallel. The boilers, of the water-tube type, are six in number, and are shared with the waterworks alongside. The concentric cables are laid underground, in wooden troughs filled with asphalte. Transformation is accomplished on the consumer's premises, and the lamps run at 72 volts. The lamps (8 c.p.) connected were 3,776 on October 1, 1891, and 21,414 on March 31, 1892.

The following items are of interest: average burning hours per lamp connected per day 1·93, which, considering that nearly all (85 per cent.) the custom consists of shops, offices, clubs, and restaurants, is very low. The average number of 8 c.p. lamps per consumer is 138. The units generated amounted to 233,712, of which 23,452 were used experimentally. The nett production was therefore 210,260, and the measured and estimated units delivered to consumers were 154,909, which gives losses from every source equivalent to 26·4 per cent. The number of units delivered to paying consumers was 145,483. The amount of coal used was about 600 tons, and coke 540 tons (coal 14s., coke 7s. per ton).

* For description of this station see *The Electrician*, Vol. XXVIII. November 13th, 1891, p. 35.

The following table gives the expenses and receipts per unit delivered to consumer:—

Expenses per B.T.U.	d.	Receipts per B.T.U.	d.
Coal	0·93	Sale of current	9·0
Wages	0·55	Sundry receipts (meters, &c.)	0·72
Upkeep of machines	0·45		
Water	0·145		
Upkeep of transformers and cables	0·27		
Repairs	0·044		
Staff	0·41		
Rents	0·12		
Sundries	0·36		
Total	3·036	Total	9·72

As the interest on capital amounts to 1·94d. per B.T.U., the profit realised is about 4·7d. per unit delivered or a total profit for the half-year of about £3,000.

LONG DISTANCE TELEPHONE LINES AND THE "K R" LAW.

The editorial columns of the *Electrical World* of February 18th contain the following remarks on the above subject:—

In this issue we print part of the inaugural address delivered last month before the institution of Electrical Engineers by Mr. W. H. Preece, the new President of the Institution. In his address Mr. Preece makes some remarks on long distance telephony, with special reference to the New York Chicago line, and goes out of his way to give American telephone engineers a lesson in their own business, which we scarcely think they need or will profit by. Mr. Preece's dogmatic statements on the theory of long distance telephony will probably not arouse much discussion in England, where long distance telephony (as we understand it here) is not, and, from the nature of the case, cannot be. But in this country his statements will not satisfy those familiar with the subject, especially as the figures he quotes in their support are most infelicitously inaccurate. For Mr. Preece with his pet K R in one hand and the £ of the British Treasury in the other, to talk of building telephone circuits with a ton or so of copper to the mile is all very well; but the telephone companies here are expected to earn dividends, and why a 600lb. wire should be used when good results and a safe margin were assured with a 435-pound wire it is difficult to see. The use of a 600-pound wire between New York and Chicago would have increased the cost of the line by nearly $50,000 for copper alone. The fact that good talking is obtained between Boston and Chicago over a line 1,200 miles long is ample proof that the size of wire used was quite large enough. Mr. Preece implies that the talking over the New York-Chicago line is not so good as that over the London-Paris line. There are those in this country who have tried both, and find the transmission on both, practically, equally good. The day that the New York-Chicago line was opened conversation was carried on between the two cities in a whisper without any difficulty whatever.

The formula for telephonic transmission, which Mr. Preece clings to so fondly and calls a law, has never met with general acceptance, nor attained the dignity of being classed with fundamental laws or formulæ from which absolute values can be determined. From the first there have been many who have denied its applicability to the case. It is an empirical formula, deduced from experiments made in the early days of telephony, before the later improvements in apparatus, lines, and methods. Undoubtedly the resistance and capacity of the circuit are factors in considering the limitations of telephonic transmission, but they are not the only ones, and we opine that the real law has yet to be discovered. Mr. Preece laid down in his law that when K R (total capacity × total resistance) reached 15,000, speech was impossible. He says that the law has enabled Paris to talk with London. If it had been applied here in the manner in which it has generally been applied up to the last year or two, it would certainly have prevented New York (to say nothing of Boston) from talking with Chicago. The original method of calculating the K R of a metallic circuit was to multiply total capacity into total resistance and divide by 4, as the capacity of an insulated loop is taken as one-quarter the capacity of the entire length of line measured against the ground. The same result is arrived at by multiplying the total capacity of one wire into its total resistance. Calculated in this way the K R of the London-Paris line is about 7,500, that of the New York-Chicago line about 33,000, and that of the Boston-Chicago line nearly 54,000. Yet New York and Boston talk with Chicago

Hosted by Google

practically with the same ease and facility that London has in talking with Paris.

Any faith that might originally have been placed in the K R law has been exploded by Mr. Preece's own modifications of it. It was originally based on Thomson's well-known formula for determining the size of conductor and dielectric of a submarine cable core with relation to the possible speed of signalling. This formula, however, has no bearing on telephonic transmission; as telephonic impulses, even little understood as they yet are, are known to be of a very different character from telegraphic signals. The original method of calculating K R, as we have already said, was to multiply total measured capacity into total measured resistance; and to allow of speech the result had to come well within certain well-defined limits. For a circuit with cables in it Mr. Preece put the limit of K R at 8,000. But when the London-Paris line, with a K R nearly approaching that figure, gave surprisingly good transmission, he saw there was something wrong with the formula. The trouble he found was that in an evenly balanced metallic circuit (especially a twisted one) electro-magnetic inertia might be neglected entirely, and, moreover, a kindly, helpful quality, M, due to extra currents from the high capacity of the submarine cable, came forward to partially eliminate K. Mr. Preece gave M a value of 0·0075 microfarads per mile, subtracted it from K and brought K down at one jump from 0·0156 to 0·0075 microfarads per mile. Since this discovery, which a little over a year ago brought the K R of the London-Paris line down to about 5,000, M has evidently increased, as Mr. Preece now gives 0·005 microfarads per mile for the K of that line. The R meets with no eliminating factor, and the Wheatstone bridge is not to be cheated of its ohms, but Mr. Preece can evidently do what he likes with K, and he places the capacity of the New York-Chicago line at 0·004 microfarads per mile, cuts that in half again, and arrives at a K R of 7,500, "which gives a result that quite accords," &c. That Mr. Preece should say that 0·0158 microfarad is "absurdly high" is rather surprising, in view of the fact that in his Paper on the London-Paris line, read before the British Associationmeeting at Cardiff in August, 1891, he gave a capacity of 0·0156 microfarad for the 400lb. wire from London to Dover. That was, of course, before M emerged from the English Channel and set to work demolishing K. It is worth noting in his Paper Mr. Preece ascribes M to the large capacity of the submaring cable in the middle of the London-Paris line. But in the New York-Chicago line there is only a mile or two of submarine cable, almost all of it at the extreme New York end. Where, then, in this case, where it cuts K down from 0·0156 to 0·004, does M come from? Of course it is very easy to keep a formula or law on its legs by introducing new factors to meet each special case, and this is what Mr. Preece has done. But at the rate he has maintained so far he will soon reach a point where he will to give K a minus value in order to keep K R within his limit, and that would be a *reducio ad absurdum*. Mr. Jacques had adopted the more simple if less scientific plan of multiplying his limit by ten, and now places K R at 45,000 for good transmission with a Hunning transmitter. In this way it will always be easy to keep a little ahead of the longest circuit operated. It is quite evident that K R is not a formula for telephonists to be guided by. The principles underlying telephonic transmission have not yet been the subject of really painstaking original investigation, or at all events no concrete results of such investigation have been published. There is a splendid field here awaiting the discoverer, and doubtless some day the fundamental laws of telephonic tranmission will be given to the world.

The telephone line between Boston and Chicago, which was successfully inaugurated last week, passes through New York, and comprises over two miles of submarine cable and about three miles of underground. The aerial line, slightly over 1,200 miles long, is of No. 8 S,W.G. copper, weighing 435lb. to the mile. The K R, by the old method of calculation, is about 54,000. By the new, we cannot say what it would be; to determine that, it would be necessary to obtain from Mr. Preece the proper value of K, which he would probably place at 0·003 microfarad per mile, or less. The transmission over the line is very good, and at the opening ceremonies even those unaccustomed to frequent use of the telephone were able to talk with Chicago without any difficulty whatever. The New York-Chicago line has several times been used for lecture purposes when it was connected to underground cable circuits several miles long, materially adding to both resistance and capacity, and bringing up the K R accordingly. Yet at these lectures as many as 40 receivers were connected in circuit and as many of the audience were enabled to listen together to speechifying from Chicago. Any metallic circuit subscriber in New York can talk through to Chicago with perfect ease, notwithstanding the length of some of the underground cables. It is worth bearing in mind that in calculating the K R of these lines no account is taken of the capacity and resistance of the switching apparatus at the terminal offices, the strong current protectors, &c. Taking these into account the K R would be considerably increased.

PARLIAMENTARY INTELLIGENCE.

HOUSE OF COMMONS—THURSDAY, MARCH 2.

THE BARRY ISLAND ELECTRIC RAILWAY BILL.

The Court of Referees, Mr. J. Shiress Will, M.P., in the chair, yesterday considered the objection of the promoters of the Barry Railway Bill, whose object is to construct a new dock, railway, tramway, to be worked by electricity, and other works, to the *locus standi* of the National Telephone Company, who petition against the Bill. Mr. Cripps, Q.C., appeared for the promoters, and Mr. Pember, Q.C., for the National Telephone Company.

Mr. PEMBER said the National Telephone Company was carrying on a business all over the kingdom. So delicate were their instruments that they would be liable to interruption if tramway companies, or similar companies, used "earth." The Post Office could tell them that the passing of a train in the electrical subway of the City and South London Railway had absolutely interfered with their instruments as far away as North Walsham in Norfolk. That being so, the Company, as licensees of the Company, were bound to come and protect themselves, and in protecting themselves protect the public, against any attempt on the part of tramway companies to use electrical power without proper precautions not to interfere with these wires.

Mr. CRIPPS: Part of this tramway would be along a public road where there are now National Telephone wires, and my friend is clearly entitled to his *locus* so far, but the rest would be on the private property of the Barry Dock Company, and there we think there should be no restriction.

Mr. CHANDOS LEIGH: We have got several cases of tramways worked by electricity, and the National Telephone Company say it might be ruination to them.

Mr. PEMBER: It is so. I cannot understand how the *locus* is disputed. There is a certain circuit round the Barry Dock, where the property belongs to the Barry Dock Company, but the Telephone Company have numerous exchanges; we lay down our wires on their property under an agreement, no doubt terminable by a certain number of weeks notice and it might be said their interest was a slight one, because they could be turned out of it at so many months notice, but this was no ground of argument.

Mr. CHANDOS LEIGH: I think the *locus* ought to be granted; I feel very strongly about it.

Mr. CRIPPS said that, taking into consideration the strong view expressed, they would not pursue their objection.

The Court thereupon allowed the *locus standi* of the Telephone Company.

LEGAL INTELLIGENCE.

Lang v. House-to-House Electric Light Company (Limited).

This was an action, at the Brompton County Court, arising out of the fatal accident to a labourer, which was referred to in our issue of November, 1892. The plaintiff was the widow of T. Piercy Lang, the labourer who was killed whilst at work on some wires belonging to the House-to-House Electric Light Company, the defendants. The plaintiff claimed £300 damages, and alleged that the cable which the deceased was handling when he met his death was insufficiently insulated.

Mr. Lyndell Bell, in stating the Plaintiff's case, said the deceased was assisting in running a service wire from the main to a house in Roland Gardens. Whilst so engaged his hand came in contact with a "live" wire, the result being death. [Counsel produced a specimen of the cable.] The husband of the Plaintiff was, he said, an ordinary labourer, and had no special knowledge of electricity. There was no doubt, whatever that his death was caused by electric shock, and the question for the jury to consider was whether it was due to any neglect on the part of the Defendant Company. The Plaintiff alleged that the cable was not properly insulated. At the inquest it was proved that some of the indiarubber had been rubbed off, but as the accident occurred after 4 o'clock on a November afternoon, it was quite impossible in the darkness for a man to discover this. The high-pressure system while doubtless more economical was more dangerous. Hence it became not merely a moral but a legal duty on the part of employers to take every possible precaution for the protection of their workmen. In this case, moreover, the poor man had no very clear knowledge, and was nevertheless entrusted with a dangerous task. The answer of the company would include a charge that the man did not obey orders and wear indiarubber gloves when handling the wires.

Mr. W. R. Payne, an employe of the Company up to October last, gave evidence to the effect that leather gloves were provided in June last, but that there was only one pair of rubber gloves available. Mr. E. C. de Segundo gave emphatic evidence as to the danger of allowing men to handle "live" 2,000 volt wires even with rubber gloves on; moreover, he thought that there was no necessity for so doing. The cable in question did not appear to him to be up to the mark, and he was surprised to hear that it had an insulation resistance of 5,000 megohms per mile. He had never had to specify for a 2,000 volt cable. Mr. C. H. Yeaman stated that on no account would he allow a workman at 25s. a week to handle a "live" 2,000 volt wire, though he had done so himself with due precautions. Mr. G. L. Addenbroke was of opinion that it was most dangerous to handle a "live" cable as had been stated. There was no difficulty in avoiding the handling of "live" wires and their handling ought to be avoided. He did not consider the cable in question properly insulated in view of the mechanical strains and atmospheric influences, it was likely to be subjected to.

For the defence Mr. Albert Gay, engineeer and manager to the Company, said the cable was of Silvertown manufacture, it was of the best

Hosted by Google

quality and had an extra covering. A letter prohibiting the touching of "live" wires without using rubber gloves was sent to the men whose duty it was to deal with the mains. Gloves had been in use two years. It was entirely inaccurate to say that only one pair was available. He believed there were half a dozen. He himself had worked on "live" cables and made joints with rubber gloves on. Lang was not a mere labourer, he was an assistant joiner. Mr. James Swinburne said that to him the cable seemed well protected. Its makers were of the highest repute. It would be perfectly safe to handle a "live" wire like it with rubber gloves, and it was continually done. No doubt there was some risk; but so there was in most things electrical. The gloves were made for the express purpose, and he himself always used them, as did his assistants. A joint could be made in a "live" wire, but it was not advisable to do it. Mr. H. M. Taylor stated that Lang could make a joint. The joint in question was made shortly after three o'clock. He then put the current on and went away, leaving Young and Lang to finish off. There were two pairs of gloves available at the time he went away. The current was put on about 3:15; the accident took place a little after four. Lang himself saw the joint done and the current put on. David Young gave evidence of Lang's knowledge of jointing, and alleged that Lang on receipt of the circular *re* rubber gloves tore it up and laughed. In cross-examination witness said he could not be positive Lang tore up the circular; it might only have been the envelope. Mr. Bell then pointed out that the Judge held Lang's copy of the circular in his hands. At this stage the Court adjourned until Thursday, March 2nd.

Yesterday (Thursday) the Court was addressed by Mr. Ruegg for the defendant, and Mr. Lynden Bell for the plaintiff. The facts were practically admitted by both sides. Upon these facts Mr. Lynden Bell for the plaintiff argued that there was negligence on the part of the Company, which entitled the widow to recover under the Employers' Liability Act; whilst Mr. Ruegg for the defendants contended that there was no negligence on the part of the Company, but that there was contributory negligence on the part of the man Lang in disregarding instructions given to him.

His HONOUR left the following questions to the jury:—Was there negligence on the part of the defendants or their servants by reason of a dangerous system of working? Did such negligence cause the accident? Was Taylor guilty of negligence in superintending the work in which the man was engaged? Was the man guilty of contributory negligence in not using the gloves? Did such negligence mainly or partly cause the accident?

After a retirement of about an hour the jury returned into Court with the following answers to the questions put to them. To the question as to whether there was negligence on the part of the defendant Company, they answered in the affirmative. To the second question—did such negligence cause the accident?—the answer was Yes. To the question as to Taylor's negligence, No. As to Lang's contributory negligence, they answered affirmatively; and as to whether his negligence mainly or partly caused the accident, they replied, Mainly.

Mr. RUEGG? That is a verdict for the defendants?

His HONOUR: Yes.

Mr. RUEGG applied for costs, urging that the case might go to appeal, and in that event it was necessary that there should be a ruling as to costs.

His HONOUR said the jury had found that there was negligence on the part of the defendants, and he should certainly not allow costs.

Donovan v. The Laing, Wharton and Down Construction Syndicate (Limited).

This was an appeal, heard before the Master of the Rolls and Lords Justices Lindley and Bowen, from a judgment delivered by Mr. Baron Pollock, in opposition to the verdict of the jury. The plaintiff claimed damages for injuries sustained through the negligence of a servant of the defendants, who, whilst in charge of a crane at a wharf, set it in motion before receiving the usual signal, knocking plaintiff down and seriously injuring him. The defence was that the crane-man, although really in the employ of the defendants, was at the time lent to the firm of Jones and Co., whose work it was that was being carried out when the accident happened. The jury gave a verdict for the plaintiff, but the judge, on further consideration, gave judgment for the defendants, on the ground that they were not liable.

The case was argued on Monday and Thursday, and eventually their lordships dismissed the appeal.

AMERICAN NOTES.

(FROM OUR OWN CORRESPONDENT.)

NEW YORK, *Feb.* 17, 1893.

Boston-Chicago Telephone Trunk Wire.—On Tuesday, February 7th, the long-distance telephone line connecting Boston and Chicago was formally opened by the Governor of Massachusetts, the members of his staff, and many other notables, who congratulated their Chicago friends, over 1,200 miles of wire, upon their being at last within speaking distance of the "Hub of the Universe." The success of the line was most marked.

The K R Law.—In view of this recent success, Mr. Preece's remarks in his inaugural address on long-distance telephony (advance sheets of which have just reached this country) have been read with considerable interest, and have received some severe criticism by American telephonists. The *Electrical World*, for instance, devotes more than a column and a-half of its editorial page in discussing Mr. Preece's views on this subject and the K R law, as enunciated by him. It would seem from the reports received in this country of Mr. Preece's remarks, that he was misinformed in regard to the details of the long-distance line between New York and Chicago, and that some of his conclusions were therefore erroneous, and have been flatly contradicted by the results obtained.

The Lamp Question.—The lamp situation remains unchanged, as Judge Colt has not yet rendered a decision in the proceedings instituted by the General Electric Company for a restraining order against the Beacon Vacuum Pump and Electrical Company, of Boston, alleged infringer of its patents. Electricians on your side of the Atlantic, where consolidation of interests have removed the cause for litigation in regard to the incandescent lamp cannot appreciate the intense interest which is aroused in this country by the questions involved; but here it evidently means either the absolute closing up of all but the Edison lamp factories at Harrison, N.J., or the total overthrow of the Edison patent. The testimony introduced by the Defendants, if proved to be true, will be the most remarkable that has ever figured in patent litigation, from the fact that it will show that Heinrich Göebel, an humble watchmaker, anticipated all that is essential of the Edison patent by 30 or more years, and this at a time when the incandescent lamp was impracticable from a commercial standpoint, by reason of the expense of generating the current by the only methods then in vogue. The Westinghouse Company has commenced an attack on the General Electric Company in the courts, and has asked for an order to the General Electric Company to show cause why the Westinghouse "separable" lamp is an infringement of the Edison patents. This is an effort on the part of the Westinghouse Company to compel the General Electric Company either to cease their claims or to prove them. The Westinghouse Company has also applied to the courts for an order to restrain the General Electric Company from bringing suit elsewhere, that is, against the Westinghouse Company's customers, pending the argument upon the order to show cause.

[According to the *Electrical World* of February 25th, a decision was given by Judge Colt on February 18th in the action brought by the General Electric Company against the Beacon Vacuum Pump and Electrical Company, of Boston. The Judge held that it was doubtful if some of the lamps alleged to have been made by Goebel were practical lamps, whilst others enveloped "with a cloud of suspicion the whole Goebel story." The prayer for a temporary suspension of the injunction was not, therefore, granted. Similar actions were to be tried at Chicago on February 20th, and at St. Louis on February 21st.—ED. *E.*]

CORRESPONDENCE.

THE YEAR-BOOK OF SCIENCE FOR 1892.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: In the review of the above book in your last issue it is complained that "The index is by no means as complete as it should be in a book of reference of this kind. The names of authors or investigators are not given in it; a very serious omission."

In justice to the publishers, who have provided the book with a very copious index of the names of the authors referred to in the book, as well as an index of the subjects treated of, I think this statement should not be allowed to pass uncontradicted. I can only suppose that the reviewer referred only to the list of subjects, and omitted to notice the index to the names of authors which immediately follows it.—Yours, &c.,

H. H. HOFFERT.

20, Hastings-road, Ealing, W., February 25, 1893.

[We regret that the second index was unaccountably overlooked by the reviewer.—ED. *E.*]

THE KELVIN WATTMETER.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: In last week's issue of *The Electrician* you make the suggestion that a transformer might be used with advantage in the shunt-circuit of the Kelvin wattmeter. Without going into the general question of the use of transformers in the fine-wire circuit of wattmeters, it may be pointed out that the advantages in this particular case are by no means obvious. In the first place the current used in the shunt-coil is so small that the making of suitable non-inductive platinoid resistances is a comparatively simple and cheap matter. If a transformer were used it would be still necessary to have a large portion of the resistance in the fine-wire circuit non-inductive, and of platinoid or other alloy with small temperature variation, as otherwise the inductance error and the temperature error would both be serious and would be difficult to estimate.

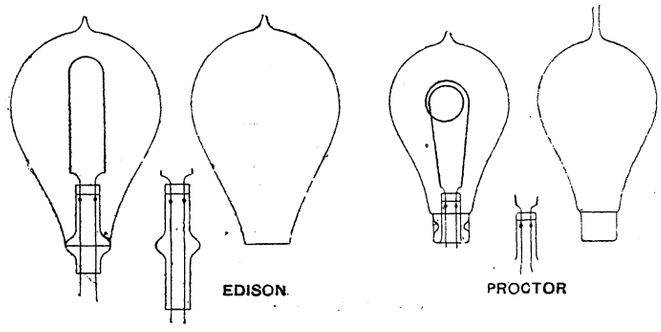
Another difficulty introduced by the use of a transformer would be the difficulty of maintaining insulation due to the large difference of potentials between the fine wire and the main coils. At present one end of the fine wire movable coils is joined directly to the main coils, and the difference of potentials between them is therefore reduced to a minimum. Another point which is apt to be overlooked is the fact that unless the moving parts of an instrument on a high tension circuit are at the same potential as the surrounding metal large errors may be introduced due to electrostatic attraction. In the Kelvin wattmeter it has been found necessary to have the movable coils in direct metallic contact with the scale and supports.—Yours, &c., ANDREW W. MEIKLE.

Cambridge-street, Glasgow, March 1, 1893.

PLATINUM IN THE CONSTRUCTION OF INCANDESCENT LAMPS.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: I think, in connection with your leaderette concerning the importance of platinum in the construction of incandescence lamps, it may interest your readers to know that about the beginning of 1891 I made several experiments with iron conducting wires for incandescence lamps. It is well known that an enamel can be made, which adheres most firmly to iron pans, &c. I thus hoped, by getting fine iron wires well



enamelled, and then bedded in a glass as nearly approaching the enamel in composition, or by bedding them in a cup-shaped piece of enamel, to which the bulb would be sealed, it might be possible to get a lamp which would maintain a good vacua. I succeeded in making one or two lamps which retained their vacua; but a little consideration of the commercial aspect of the question, which unfortunately is the stumbling block of almost all inventions, soon showed that at the present price of incandescence lamps, if the new lamp gave, say, 10 per cent. more loss by bad vacua and defective lamps, this loss would be more than sufficient to pay for the whole platinum in the lamp as then made.

The copper-tin alloy, which you quote from a German journal, seems to be much the same as Captain Walters' metal, which I have tried but with only very unsatisfactory results.

From the platinum point of view, the Edison American lamp has always seemed to me as nearly perfect as possible; but, unfortunately, the difficulty in making what is technically termed the improved joint (the form of joint by which the stem is joined to the bulb) has been more than sufficient to counteract the economy in platinum, it thus has, to a great extent, been superseded by the late Mr. C. H. Gimingham's lamp, although this contains three or four times as much platinum.

It is often found that this latter lamp, when used in factories where there is much vibration, is liable to shake loose from its support; and in 1891 I was requested to investigate whether it was not possible to alter the lamp in such a manner as to enable the collar to have a better hold on it, with the result that in September, 1891, I registered a lamp which has since been adopted by this Company.

From the enclosed sketches you will see that I have succeeded in so modifying the original Edison form of lamp as to retain the advantage of only requiring a very small amount of platinum, and have adopted a joint between the inner glass stem, and the bulb, which is not only extremely easy to make, but also enables bulbs with a relatively large difference between their coefficients of expansion, and the interior glass stems being used without cracking, a fact which, in many cases, is of great convenience.

I think, considering the very small amount of platinum used in the above lamp, there is very little room for economy unless a substitute is found in every way equal to the platinum.—Yours, &c., C. FARADAY PROCTOR,

Ingénieur et Chef de Fabrication, Cie. Générale des Lampes Incandescentes, (Edison and Swan), Paris.

Rue de l'Orme, Ivry sur Seine, February 25, 1893.

"ELECTRICAL REVIEW" AND "SCIENCE SIFTINGS" DEFENCE FUND.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: In view of the litigation now pending between the respective proprietors of the two newspapers, the *Electrical Review* and *Science Siftings*, on the one hand, and C. B. Harness and the Medical Battery Company on the other, arising out of criticisms in these papers on the proceedings of Mr. Harness and the Company before mentioned, there is a widespread feeling in the medical and electrical professions that the proprietors of these papers should receive ample pecuniary assistance in their public-spirited endeavour to have the issues raised fully investigated in the Law Courts, which will necessarily involve a considerable expenditure.

A Committee, consisting of the following gentlemen, has been formed for the purpose of raising a fund for the before-mentioned purposes:—Lord Armstrong, F.R.S., Mr. Latimer Clark, F.R.S., Prof. G. Carey Foster, F.R.S., Dr. John Hopkinson, F.R.S., Prof. G. B. Howes, Mr. W. M. Mordey, Prof. J. Perry, F.R.S., Mr. W. H. Preece, F.R.S., Sir David Salomons, Bart., and Major-General Webber, C.B.

Hon. Trustees, Mr. A. P. Trotter, B.A., 2, Victoria-mansions, 28, Victoria-street, Westminster, S.W.; and Mr. J. H. Thornton, Chartered Accountant, 227, Winchester House, Old Broad-street, E.C.

Hon. Secretary, Mr. James Swinburne, 49, Queen's-road, Wimbledon, S.W.

The issues raised are of the greatest possible importance, both to the public and to the medical profession, involving as they do, the question of the *bonâ*, or *malâ*, *fides* of certain methods of treating disease by electrical or alleged electrical processes, which have been and are now being carrried out and extensively advertised under the auspices of Mr. C. B. Harness and the Company with which he is identified. A preliminary action has already been brought by Dr. Tibbits, at Mr. Harness's expense, against the *Electrical Review* for alleged libel, as he had been strongly censured in that paper for associating himself with the system alluded to. The proprietors of the *Electrical Review* obtained a verdict with costs against Dr. Tibbits, but even if the *Electrical Review* succeeds in recovering the costs from Dr. Tibbits, the costs recoverable will only meet a portion of the expenditure necessarily incurred. It is intended to devote a portion of the amount subscribed to the payment of these expenses, which have been the result of a disinterested—and, so far, a successful—attempt to protect the

Hosted by Google

public. The Committee further intend to apply such portions of the amount as they may, in their discretion, consider advisable, to pay, or contribute to the payment of, the expenses which have been, or may be, incurred by the proprietors of the *Electrical Review*, or by those of *Science Siftings*, in connection with this litigation. Any surplus remaining after such payments have been made, may, at the discretion of the Committee, be employed as the Committee may determine in connection with any further proceedings that may be taken in the matter.

It is believed that members of the medical profession especially will be glad of the opportunity of expressing, by a liberal support of the fund, their disapprobation of the view put forward by Dr. Tibbits's counsel, that the article, in censuring Dr. Tibbits's, was, in his person, attacking the medical profession generally. If your numerous readers are willing to subscribe to the fund, and to give it the benefit of their influence and support, they are requested to forward the amount of their subscription by cheque, payable to Mr. James Swinburne (Defence Fund), and crossed London and South-Western Bank, Wimbledon Branch.—Yours, &c.,

JAMES SWINBURNE, Hon. Secretary.

49, Queen's-road, Wimbledon.

GRAPHITE RESISTANCES.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: In your issue of February 24th you mention as novelties resistances made of plumbago, and mixtures of plumbago and clay. May I draw your attention to the fact that a Paper (notice enclosed) was read before the Ashmolean Society of Oxford, February 11, 1889, on high resistances made of different mixtures of plumbago, carbon, oxide of lead, plaster of Paris, and crucible clay, by Mr. Frederick Smith, M.A., Trinity College. Mr. Smith's earliest resistances were made by compressing the composition in steel split tubes in the hydraulic press. Also a short note on his powder resistances was published in the *Telegraphic Journal* for 1879, page 86.—Yours, &c,

J. M.

A NEW ELECTRIC HORN.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: In yesterday's *Electrician* I notice an article suggesting that electric bells might be worked from an electric lighting current. In connection with this subject I beg to bring before your notice an "electric horn," with which I have recently carried out a series of experiments, to take the place of electric bells or gongs, &c., where an alternating current of electricity is available. The apparatus is based upon the principle of the telephone receiver, and consists, in its simplest form, of a disc of sheet iron placed in front of one of the poles of an electro-magnet, the coil of the latter being arranged to take an alternating current of 100 volts.

The method of working is as follows:—When the current is switched on the reversals of magnetism produced in the iron core by the current cause a corresponding number of vibrations in the disc. Thus, if a current with 200 alternations per second be employed, the disc gives 200 complete vibrations per second, and produces a note corresponding in pitch with this number of vibrations. With a current of a given number of alternations, the pitch of the note is constant, no matter what the diameter or thickness of the disc, since the latter, in all of these, is obliged to vibrate at the same rate. The timbre and intensity of the sound, however, can be made to vary in a number of ways. In order to obtain an intense sound with a small amount of current, the diaphragm, or disc, must strike, whilst vibrating, the iron core or some other body.

In one form of the apparatus that I have, a sound, loud enough for domestic purposes is obtained with about one ampere of current. It will be observed that in this apparatus there is no break in the current, as occurs in the ordinary electric bell.—Yours, &c.,

A. B. WOAKES.

Harley-street, W., February 25, 1893.

USEFUL FORMULÆ.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: In the letter you published from me on February 3rd, about the loss of energy in copper conductors, a slip occurred which I hasten to correct. When a current density (amperes per square inch) different from 1,000 is used the result obtained from the rule must be multiplied by the *square* of the current density and divided by the *square* of 1,000.

Let me add another easily remembered fact, which is useful in approximate calculations:—

The double conductor of a light or power circuit at a current density of 1,000 uses up the electric pressure at the rate of 5 volts per 100 yards, or about 90 volts per mile; and the volts used up in the conductor, per 100 yards or per mile, vary directly as the current density.

Yours, &c., GEORGE FORBES.

R.M.S. "Majestic," February 10, 1893.

"THAT BLESSED WORD, 'INSTALLATION'!"

TO THE EDITOR OF THE ELECTRICIAN.

SIR: My first thought on seeing Mr. Selby-Bigge's letter was to make fun of it, but it would perhaps be better to treat his communication seriously; and, as he has "found this much-abused word most useful" at University College, Oxford, I think we ought to petition the authorities for its retention there for Mr. Bigge's sole use and benefit.

A "whole installation consisting of these items [wiring, fittings, lamps, holders, and glass ware] at a fixed price per light" is evidently intended to mean something definite at Oxford; but in other parts of the country the word, which my pen refuses to put on paper except in a quotation, may include all Mr. Bigge's "items" plus underground mains, plus dynamos, plus secondary cells, plus steam-engines and boilers, or turbines or water wheels!

I have known many cases where it was proposed that a "whole installation at a fixed price per light" should consist of wiring only; and, even in these circumstances, I was not satisfied till I had particulars of wires, casings, cut-outs, switches, ceiling plates, and blocks, &c. Sometimes cutting away and making good form no part of the whole ————; and I hope Mr Bigge realises that the word which answers his purpose so well at Oxford has a vagueness about it elsewhere, which his exposition does not help us to get rid of; and, to borrow his words, "I do not know what single word we could have employed" to describe his contribution to the debate!—Yours, &c.,

Twyford, Berks, February 28, 1893. WM. H. MASSEY.

TRADE NOTES AND NOTICES.

[*Notices for insertion under the above heading must reach the Office not later than first post Thursday morning. New Catalogues, Price Lists, and similar matter should be sent early in the week.*]

Our readers are reminded that the 1893 Edition of "THE ELECTRICIAN" Electrical Trades' Directory and Handbook is NOW READY. This useful book contains over 1,000 pages, and several new and handy features have been added. The price of the Directory and Handbook is 7s. 6d. Postage in the United Kingdom, 9d.; abroad, 1s. 4d.

TENDERS INVITED.—Moodie's Gold Mining and Exploration Company (Limited), of Pietermaritzburg, Natal, invite tenders for the supply and erection at Barberton, S. A. R., of plant and machinery for generating and transmitting 250 H.P. by electricity to various sub-companies. Plans can be seen at the various offices of the Company (in London, at 8, Old Jewry, E.C.), and tenders must be sent in to the head office at Pietermaritzburg by noon on May 3rd next, and a duplicate copy lodged with the London office as above. Further particulars will be found in our advertisement columns.

———— Tenders are invited by the Trustees of the Town and Harbour of Whitehaven for the supplying and laying insulated conductors, required in connection with their central electric lighting station. All information can be obtained of Dr. John

Hosted by Google

Hopkinson, 5, Victoria-street, Westminster, S.W., and from Mr. John Collins, Secretary to the Trustees to whom tenders must be delivered by 10 a.m. on the 22nd instant. Further particulars appear in our advertisement columns.

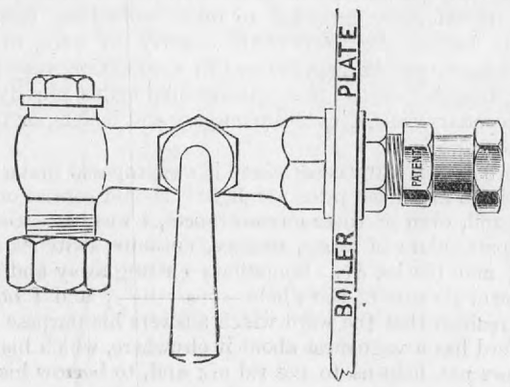
——— It will be seen by our advertisement columns that the Corporation of Dewsbury invite tenders for the construction, supply, and laying down of the necessary plant and mains for the supply of electricity in the borough. Tenders are to be delivered at the office of the Town Clerk not later than the 23rd inst.

——— The Wallasey Local Board invite tenders for diverting the route of the telegraph line used in connection with the water-level electrical gauge at the Wallasey Waterworks, and for renewing the wire for a distance of 1,220 yards. Tenders must be in by 5 o'clock on the 14th instant.

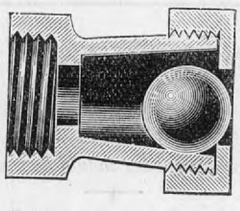
Tenders Accepted.—Messrs. Norman and Son, of Glasgow, have obtained the contract for the electric lighting of the new Glenburn Hydropathy at Craigmore, Buteshire.

Messrs. Crompton and Co.'s Motor Catalogue. — Uniform with their recently issued dynamo catalogue, Messrs. Crompton and Co. have compiled a very useful book of notes, data, and specimen estimates of costs relating to the electric transmission of power. The design of the plant for different purposes and selection of the best size of conductor are discussed in a very practical and business-like manner, and examples showing the effect of different sizes of conductors on the loss in the line, and on the cost of the plant are very clearly compared.

Automatic Water-Gauge Stopper.—Mr. James Baldwin, of Keighley, has introduced an automatic valve which may be fitted inside the boiler to any water gauge. Should the water gauge glass inadvertently burst, or the gauges themselves by any means be broken off, the escape of steam and water is at once stopped by the



safety automatic stopper, thus preventing the engineer and stoker from being seriously injured, and the immediate blowing down of the boiler and consequent loss. When the glass breaks the escape



of steam and water is instantly stopped, and after the taps are closed and the gauge glass refixed, the automatic stopper, not being perfectly steam and water tight, the consequent small leakage causes an equal pressure on each side of the balls, and they then roll back to their former position automatically.

Messrs. Rashleigh, Phipps and Co. (102, Oxford-street, W.).—This firm have recently secured contracts for a number of lighting installations, including the new works at Canning Town of the Lamson Paragon Paper Supply Company (complete plant), Messrs. Mooney and Co.'s new depôt at 19, High Holborn, W.C.; W. G. Curryer's boot depôt, 69, Oxford-street, W.; the new depôt for Messrs. Hudson Brothers, 40, High-street, Kensington; Mr. L. S. Myers, 5, Grafton-street; Dr. Luff, 31, Weymouth-street; Dr. Hutchinson, 1, Park-crescent; Dr. Dolamore, 37, Queen Anne-street; Dr. W. Adams Frost, 17, Queen Anne-streeet; and for new batteries at Messrs. Marshall and Snelgrove's large premises in Oxford-street, to supply additional lighting. Additional City work includes the Buenos Ayres Great Southern Railway Company, 6 and 7, Finsbury-circus, and Messrs. Shepheards, 31 and 32, Finsbury circus.

Messrs. Ernest Scott and Mountain (Limited).—This firm inform us that they have obtained the contract for the electric lighting of Craig House, Edinburgh, which is described as one of the largest private lunatic asylums in the kingdom. The firm also report sustained activity in their electrical department, a number of important contracts having recently been secured.

Lamp-Holders.—Messrs. Henry F. Shippey and Co. notify that they are in a position to supply some well-known types of lamp-holders to Continental and other users (where patent rights do not apply) at much under ordinary prices. Further particulars are given in our advertisement pages.

Revolving Sprinkler.—Messrs. Edwards Brothers' patent automatic revolving sprinkler, with elastic compensating valve, was shown in the library of the Royal Institution on Friday last. This fire extinguishing apparatus depends upon the action of fusible metal and a rubber valve, and seems to present several advantages.

Britannia Company.—This Company are introducing a new speciality in radial drills, illustrated particulars of which can be obtained on request.

Messrs. Swinburne and Co.'s Catalogue.—We have received a catalogue and price list of Messrs. Swinburne and Co.'s manufactures which now include both dynamos and alternators. We note that the latter are "wound for 100 volts and 100 P. P. S." Messrs. Swinburne and Co. evidently avoid the symbol ∿ lest it might be imagined that they are offering Mordey machines. While not abating in any degree their advocacy of Hedgehog transformers, backed up as they are by a sheet of testimonials giving unqualified approval of them, a "Cylinder" transformer has been brought out to meet the requirements of those who prefer closed-circuit transformers. It is claimed that the weight of each type is very small. Wattmeters with ebonite bodies, electrostatic voltmeters, central-station voltmeters, and numerous laboratory instruments, are described. Amongst these is an electrostatic voltmeter, or watt-meter, which is said to read to half a volt in 2,000, the Bourne galvanometer, switch resistance box, and cable-testing plant. A 120-kilowatt set of the latter, capable of testing cable up to 40,000 volts, has been supplied by Messrs. Swinburne and Co. to the Silvertown works.

Calendar.—The Postal Telegraph Cable Company, of New York, whose service is in connection with the Commercial Company's cables, send us a hanging pad calendar for 1893, giving a map outline sketch of the Company's system throughout the States.

Aberdeen.—The Town Council have approved the plans of the new buildings for the central station, to be erected in Cotton-street, adjoining the gas works. The buildings will cost about £3,500.

Batavia Exhibition.—We learn that British electrical firms are holding aloof from this exhibition; it may be because exhibitions have been somewhat overdone. It is, however, regrettable to learn that the exhibition at Batavia is likely to prove an exclusively German advertising medium. German electrical firms offer to supply the electric lighting plant, and to provide sufficient petroleum motors to drive the whole of the machinery at the exhibition. Should the exhibition ultimately prove a profitable medium for the introduction of German goods, British manufacturers will have, of course, themselves only to blame. Plans of the exhibition, grounds, and buildings, and all available particulars can be obtained of Messrs. J. Birch and Co., 10 and 11, Queen-street Place, London, E.C. Some particulars of the scope of the exhibition, and exhibits likely to prove acceptable, we gave on page 490 of our last issue. Group XV., Class 3, is for electrical machinery and motors, dynamos, lamps, electric tramways, lighting apparatus, telephone and telegraph materials, bells, and accessories.

Bombay.—The Government Dockyard has recently been lighted by electricity, under the supervision of Mr. G. F. Mackrow, of the Royal Indian Marine. The generating plant consists of two Siemens dynamos, driven by a Marshall 32-H.P. engine, and the installation includes 64 L31 type E.P.S. accumulators. The fittings and accessories have been arranged by Mr. H. Gill, electrician to the Dockyard authorities, and the light has proved a complete success. A 7,000-c.p. lamp, fixed 70ft. from the ground, will also be erected at the head of the Duncan Dock as soon as the works at the dock are completed.

Bournemouth.—A tender has been received by the Town Council from Messrs. Goddard, Massey, Warner and Co., for the additional works required for the electric lighting of the pier and gardens, the tender amounting to £1,453. 10s. The Financial Committee of the Council recommended the postponement of the question of supplying 70 lamps for the inside of the pier shelters, but recommended that the extra-sized mains necessary to carry the current should be provided at a cost of £178, that the necessary mains for lighting the fountains be supplied at a cost of £184, that two dynamos be supplied at a cost of £161, and that a lamp be

Hosted by Google

provided for the pier at a cost of £12. 10s. A member of the Council having complained that the electric lighting expenses were becoming excessive, the Mayor reminded him that £4,000 was the original estimate, and that up to the present, although additional work had been approved, only £3,600 had been ordered to be expended. The recommendations of the Committee were approved.

BRISTOL.—The Electrical Committee of the Town Council on Friday last, in conformity with the powers conferred upon them by the Local Government Board, decided upon borrowing £16,000 for electric lighting purposes at 3½ per cent.

CAGLIARI.—At the last meeting of the Cagliari Gas and Water Company the Chairman, Mr. John Aird, M.P., stated that they had authorised their manager in Sardinia to endeavour to make arrangements with the authorities for dealing with the matter of the electric light.

CARDIFF.—A deputation, consisting of the Mayor of Cardiff, Alderman Jacobs, and Mr. Harpur, borough engineer, have waited upon the Local Government Board for the purpose of inviting the Board to hold an inquiry in Cardiff, with the object of authorising the Corporation to borrow the necessary money to carry out their electric lighting scheme. It is most probable that the Great Western Railway Company will give the Corporation facilities for sidings into their Central Station at the works at Canton Common.

DUNDEE.—The Corporation's central station was illuminated for the first time on Wednesday last week by the electric light, and the effect is represented to have been excellent. The light was supplied from the battery installation which has been put down.

FARNWORTH.—On Saturday last the extensive premises of the Farnworth and Cursley Industrial Societies in the Market-street, Farnworth, were lighted by electricity. Messrs. Royce and Co. supplied and erected the plant for the installation, which comprises a Royce compound-wound dynamo and Marshall engine and boiler, On the occasion of the inauguration a variety of cooking and heating appliances were shown and, as usual, created considerable interest.

HULL.—It is in contemplation to considerably extend the electric lighting installation which the Corporation have recently inaugurated, as the demand for the light has considerably exceeded expectations. New mains will shortly be laid on the west side of the Whitefriargate Bridge, in order to supply the light over a considerably extended area. A report, prepared by Mr. F. Harman Lewis, the borough electrical engineer, estimating that the extensions would cost between £9,000 and £10,000, has been, after discussion, approved, and power has been given to the Chairman of the Lighting Committee and the Borough Electrical Engineer in future to dispose, without consultation with the Board, of all applications for the light within a distance of 60 feet from the main distributors.

HUNTLY.—The Board of Commissioners have been in negotiation for the purchase of the rights of the gas company, but there is a general feeling that it would be an unwise step for the Commissioners to become owners of the Company's rights, seeing that electric lighting is making such rapid progress. At the last meeting of the Board it was decided to leave the matter over for further consideration at a future date.

ISLINGTON.—The Vestry at their last meeting adopted the report of the Special Lighting Committee recommending the Vestry to decline to give its consent to the promotion of the Islington Electric Lighting Order (1893) by the County of London Electric Lighting Company (Limited), and also against the promotion of the St. Mary, Islington (North), Electricity Supply Order (1893) by the Holloway Electricity Supply Company (Limited).

KENSINGTON.—The Highways Committee have reported upon the Hammersmith electric lighting scheme promoted by the local authorities, and state that they have submitted some few amendments to the Board of Trade. It is proposed to except Hammersmith Bridge from the area of supply. In reference to the proposed transfer of powers possessed by the Chelsea Electricity Supply Company, under their South Kensington Electric Lighting Order of 1889, to the Kensington and Knightsbridge Company, the Committe propose to insist upon provision being made that the Chelsea Company shall not have power under their transfer scheme to break up the roads to obtain access to their transformer station at Egerton-gardens-mews; and the Committee further propose to insert a clause with this object in the transfer arrangements. The London County Council have ordered a petition to be presented against the Bill. The proposal by the Kensington and Knightsbridge Company for an extension of mains has received sanction.

LECTURES.—Lectures on electricity and its various applications have recently been delivered by Dr. Joseph M'Grath at Dublin, Rev. A. C. Henderson, at Dundee, Mr. S. Vyle at Nottingham, Mr. C. P. Goode at Buxton, Mr. F. G. Baily at University College, Liverpool, and Mr. T. C. Fulton at Glasgow.

LEGAL.—An action was brought on Friday last at the Clerkenwell County Court against Messrs. H. and J. Read and J. Bailey, amusement contractors at the Agricultural Hall, Islington, N., for £15. 14s, for 31 weeks' hire of 100 yards of electric cable. The case was chiefly interesting from the fact that the plaintiff, a Mr. Trickett, had entered into an arrangement with the Agricultural Hall Company, the particulars of which are shown in the plaintiff's evidence, which was to the effect that from November, 1890, to August, 1891, he had the sole right of fitting electric light at the Agricultural Hall, and he supplied exhibitors at the several exhibitions held there during that time. In December, 1890, he lent the defendants some electric light cable for six weeks, during the run of the World's Fair. He charged them 10s. a week, and that sum they paid. In May, 1891, the Military Tournament was held, and he was engaged in fitting up electric light for exhibitors. He had not sufficient cable, and borrowed some from the defendants. At the end of seven weeks he returned the cable, a sum of £3. 10s. being due to defendants for the loan. He was unable to pay that, and still owed Messrs. Read and Bailey £2. 6s. When the World's Fair was over the defendants did not return his cable, although he applied for it, and they still had it. The judge ordered the return of the cable, and allowed the plaintiff £2. 6s. damages, to be paid over to the defendants. We have frequently alluded to the meagre character of the electrical installations at the Agricultural Hall, where many favourable opportunities present themselves for creditable electrical work being done; but the nature of such work can scarcely be wondered at when primitive arrangements like those disclosed in the proceedings in this action are entered into by a wealthy corporation like the Agricultural Hall Company (Limited).

ROTHERHAM.—A resolution is to be proposed at the next meeting of the Town Council that a special committee be appointed to inquire into and report upon the cost of the electric lighting plant, a suitable site for a lighting station, the probable revenue, and to obtain information likely to assist the Council in deciding whether it is advisable to instal the electric light in the borough.

SHOREDITCH.—The Select Committee of the Shoreditch Vestry have reported upon the advisability of obtaining a site in Pitfield-street, Hoxton, for the combined purposes of an electric lighting station, baths and wash-houses, technical schools, and free library. It is stated that the entire scheme will necessitate an expenditure of more than £34,000. The matter will be discussed at the next meeting of the vestry.

SOUTHAMPTON.—The Free Libraries Committee presented their report at the last meeting of the Town Council, and strongly recommended that the public library be lighted by electricity in accordance with the report prepared by Mr. J. G. W. Aldridge, and that application be made to the Local Government Board for sanction to borrow £400 for this purpose. The report was adopted.——The Harbour Board have accepted a tender from Messrs. Statter and Co. for £25, for giving additional width to the culverts for the electric mains, enabling the mains to be used for lighting purposes if required. It was also decided to light the clock at the pier entrance by electricity.——We understand that it has been decided to light the whole of the Southampton Docks with electricity, and that strenuous efforts are being made to complete a portion of the installation by to-morrow, to celebrate the arrival of the "New York," the first vessel of the new American mail service. The outside lights are to be arc lamps on poles about 55ft. high, and incandescents will be used for the interior lighting. The generating station (which is now practically complete) is on the dock premises. The electric light is to be extended to the new baggage station and refrigerator vaults.

THEATRE LIGHTING.—Messrs. T. L. Hemming and Co. have obtained a contract for the electric lighting of the Queen's Theatre, Snow Hill, Birmingham, which, when completed, will, it is represented, be one of the largest electric lighting installations in the Midlands.

PATENT RECORD.

A record of Applications for Patents and Patent Specifications Published is compiled for this journal by MR. J. C. CHAPMAN, *Fel. Chartered Inst. Patent Agents, of 70, Chancery-lane, W.C., from whom any information on the subject may be obtained.*

APPLICATIONS FOR PATENTS.

NOTE.—*The Specifications of Applications for Patents are not open to public inspection until after the acceptance of the complete specification. The names within parentheses are those of communicators of inventions, or where complete specification accompanies application an asterisk is suffixed.*

COMPANIES' MEETINGS & REPORTS.

Telegraph Construction and Maintenance Company (Limited).

The twenty-ninth ordinary general meeting of the members of the Telegraph Construction and Maintenance Company (Limited) was held at the offices of the Company, 38, Old Broad-street, on Tuesday, February 28th, Sir George Elliot, Bart., presiding.

The MANAGING DIRECTOR (Mr. Wm. Shuter) read the notice convening the meeting and the minutes of the previous meetings, the latter being confirmed and signed by the Chairman as correct.

The report of the Directors and statement of accounts were taken as read.

The CHAIRMAN said: Gentlemen, I am not going to make a long story. I never do at these meetings. I dare say that that part of the report which deals with the reduction of dividend, which we have been able to pay with unusual regularity for many years, has most attracted the attention of some of the shareholders. But while we sympathise with you in these circumstances, there is nothing, I think, to cause surprise or uneasiness. It is mainly due to the exceptional year which we have passed through with regard to cable operations, no large works having been undertaken. It is also in part due to a falling off in our general business. The cause of both, I think, is not far to seek, that is to say, the general depression which has affected trade in all its branches, from the highest to the lowest, but which there is no reason to believe, so far as we are able to judge, will be of a permanent character. There is work on hand at present, and we hope that there is some in prospect during the year. For this the Company has considerable stocks laid in. We have taken advantage of the comparatively slack time to introduce improvements into our plant and appliances at both our factories, all tending to increase their capacity for work, and in the direction of economical expenditure. I now beg to move:

"*That the report and accounts of the Directors to December 31, 1892, submitted to this meeting be, and the same are hereby, received and adopted, and that a dividend of 24s. per share, in addition to the 12s. a share interest or interim dividend, paid to June 30, 1892, be paid on all the shares of the Company, such dividend to be paid free of income tax.*"

Mr. G. W. CAMPBELL seconded the motion, which was carried unanimously, and without discussion.

The CHAIRMAN proposed, and Admiral Sir GEORGE RICHARDS seconded, the re-election of the retiring Directors, Mr. James Pender and Sir Robert G. W. Herbert.

The motion was agreed to *nem. con.*

Mr. GIBSON proposed, and Mr. CROFT seconded, the re-appointment of the auditors, Messrs. John Gane and P. A. Glegg.

The motion was carried unanimously.

Mr. GIBSON proposed, and Sir HENRY GOOCH, Bart., seconded, a vote of thanks to the Chairman, the other Directors, and the officers of the Company.

The vote having been cordially passed, the CHAIRMAN expressed his acknowledgement, and the proceedings ended.

Chelsea Electricity Supply Company (Limited).

The annual ordinary general meeting of this Company was held yesterday at their Central Station, Draycott-place, S.W., Mr. J. Irving Courtenay in the chair.

The SECRETARY (Mr. S. J. Cluer) having read the notice convening the meeting,

The CHAIRMAN said: Before moving the adoption of the report and accounts, I will direct your attention to some points that seem to me worthy of special consideration, and will say a few words on the general position of the Company. The net revenue for the year, after deducting debenture interest, is £1,336. 2s. 7d., out of which it is proposed to pay a dividend on the ordinary shares of 2½ per cent. This is not a large dividend, but it is in addition to the payment of a heavy debenture interest, and may be taken as an earnest of the future. You are aware that a considerable portion of the Company's capital is in the form of debentures. I will point out here that the net profits in 1891 were only 7½ per cent. of the gross, but in 1892 the net profits were 31 per cent. of the gross. The improvement in the Company's position, which we looked forward to, has to some extent been attained, and you will observe that the gross revenue approximates to the estimate I gave last year. The substantial progress made each year in the profits is shown by the fact that the debenture interest provided for in the last three years was in 1890 £530, in 1891 £1,206, and in 1892 £1,843, in addition to the net profit just mentioned. You will notice that as our capital expenditure has increased so also have our profits increased in a much larger proportion. The increase in capital expenditure is moderate in comparison with the figure it may reach before we arrive at the limit of profitable investment in Chelsea. The capital expenditure equals £2. 6s. 6d. per lamp installed, which will compare favourably with the capital outlay of any other electric lighting company. We have increased our lamps during last year without any large extension of the mains, and the percentage of increase in revenue has been nearly as large as the increase in the number of lamps. The other items in which the capital has been laid out have entirely justified the expenditure by the benefit already reaped, and we have the best reasons for expecting a still larger return on this expenditure during the current year. Besides some extension in mains,

Hosted by Google

the enlargement of existing mains, and the necessary addition to our stock of meters we have added to our plant two boilers and a pair of feed-water heaters: we built an extra bunker for the storing of coal; also an additional exit from the engine-room in case of accident, and made some additions and alterations to all the boilers which have been productive of large economy in working. We have enlarged the building of our Clabon Mews Sub-station and placed there an additional continuous-current transformer. These transformers were supplied by the Electric Construction Corporation (Limited), and have continued to work in an eminently satisfactory manner. They are used in addition to the accumulator plant and not in substitution for it, and we have found the combination entirely fulfil the expectations formed at the time of the original design of the system by Mr. Frank King, a system which enables us to afford our customers a regularity of supply of a quality nowhere surpassed. The plant has all been maintained in a thorough condition; indeed, the nature of the business is such that were this not done the supply could not be kept up. The storage batteries are in excellent condition, and the mains of Callender's bitumen cable have stood the test of now nearly four years underground, the insulation being still quite satisfactory. On a former occasion when I addressed you I alluded to the heavy consumption of coal, and stated that it was not due, in my opinion, to any fault of the Chelsea system. The words I then used are now being justified. The Directors have continued to give unremitting attention to this point, and have succeeded, with the able assistance of Mr. Frank King, who has been appointed Managing Engineer, in tracing the cause and remedying the defects in the plant. Some of the improvements suggested and carried out by Mr. King were not completed very early in the year 1892, and we are therefore warranted in looking for better results at the end of this year. With the experience gained we do not doubt that further economies can be made, As you will have seen in the report of the Directors, the amount paid for coal in 1892 is 9½ per cent. less than that paid in 1891, although the amount of electricity sold is 23 per cent. more in 1892 than in the previous year. Not only has there been a saving in coal but there has been greater economy all along the line. The cost of coal, water, and engine-room stores, taken together, has been 1d. less per unit of electricity sold, and the total cost of the unit, including all general charges, has been 1½d. per unit less than in 1891. You will expect to hear something from me regarding the decision in the law courts on the three-wire system. In Chelsea our supply is on two wires only, and in the small portion of South Kensington served by this Company the system is such that it is our belief that we cannot be brought under the operation of Mr. Hopkinson's patent. The proposed transfer of the Kensington portion of our area was the cause of the extraordinary general meeting held on the 14th ult., when the policy of the Directors in regard to that matter was unanimously approved. I wish it to be distinctly understood that this transaction is strictly limited to the small portion of our area at Kensington, and does not in any way deal with the Chelsea district. As stated at that meeting, the Directors consider that the transfer will be beneficial to both Companies, owing to the position of the two generating stations relatively to the area. The price agreed upon is a fair one, and the capital thus set free will be of material assistance in extensions in our Chelsea area, so as to cope with the demands arising in the immediate future. The prospects of the Company are now better than ever, both as regards profits and increase of business. The district in which our mains are laid is rapidly filling up with customers, and no one when once supplied by our system cares to discontinue its use. Close around us new houses are everywhere being built, and in many of them no provision is made for gas, such is the confidence earned by careful attention to the quality of the supply. Presidents who have tried several systems say that none is better than that of our Company. You will thus see that we cannot stand still, but must be always moving forward, using strict economy as to the direction in which capital is spent, and continuing to make such additions and improvements in plant as will ensure the largest saving in the every day work of supply. We have a good future before us if we succeed in making judicious use of our opportunities, and I hope that our endeavours will meet with cordial support from our shareholders. I now beg to move—

"*That the report of the Directors and the statement of accounts to March 31, 1892, now before the meeting, be and they are hereby adopted, and that the payment of a dividend for the year 1892 at the rate of 2½ per cent per annum on the ordinary share capital of the Company be and is hereby approved, to be made payable on April 16th.*"

The DEPUTY-CHAIRMAN (Major-General Webber, C.B.) seconded the motion, remarking that he fully endorsed all that the Ohairman had said with reference to what had occurred during the past year, and to the improvements which had been made in the Company's system. These improvements had been the growth of previous years' experience, and had fully come up to their expectations; and he believed they would answer those expectations in the future even to a greater degree than the Chairman had ventured to foretell.

The CHAIRMAN expressed his readiness to answer any questions; but none being put, he submitted the resolution in the usual manner, and it was carried unanimously.

On the motion of the CHAIRMAN, seconded by Mr. JILLINGS, the retiring Directors, Sir George Prescott, Bart., and Mr. Emile Garcke, were re-elected, as were also the auditors, Messrs. Cooper, Brothers and Co.

An extraordinary general meeting was held subsequently to consider the confirmation of the subjoined resolution, which was passed at the extraordinary general meeting on the 14th ult.:—

"*That the Bill proposed to be introduced in Parliament in the ensuing session, and now laid before this meeting, intituled 'A Bill for confirming an agreement for the transfer to the Kensington and Knightsbridge Electric Lighting Company (Limited) of the undertaking of the Chelsea Electricity Supply Company (Limited), authorised by the South Kensington Electric Lighting Order, 1889,' be, and the same is hereby approved, subject to all such additions, alterations, and variations as Parliament may think fit to make therein.*"

The CHAIRMAN said he did not intend to trouble them with any further remarks on the resolution, having spoken on the subject at the meeting on the 14th ult., and having already made some observations on it at their first meeting that day. He, therefore, formally moved the confirmation of the resolution.

Sir GEORGE PRESCOTT, Bart., seconded the motion, which was unanimously adopted.

A vote of thanks to the Chairman and Directors was then passed, after which the meeting separated.

Liverpool Electric Supply Company (Limited).

The tenth annual ordinary general meeting of the shareholders of this Company was held on Friday in the Exchange-buildings, Tithebarn-street, Mr. A. H. Holme presiding.

In proposing the adoption of the Directors' report (which appears below), the CHAIRMAN said: Gentlemen, you will see from the report that the business of the Company has very largely increased, the number of lamps we are supplying at present being 20,254, as against 14,966 last year, which I am sure it must be a source of satisfaction to you to know, more especially as with the increase of business we are able to give you an increased dividend. We have, of course, to provide for other things out of our gross profit, and we have written off £4,099 for depreciation, and placed £2,000 to the renewal fund, and this leaves us, after adding the balance brought forward, with £11,421. 19s. 11d. We propose out of this sum to pay a dividend at the rate of 5 per cent. per annum, which will take £8,621, to add £1,500 to the reserve fund, and to carry forward £1,300 to next year's account. We think that is as much as we can prudently afford, and we think we have allowed quite margin enough for all contingencies, and that is an honest dividend on the face of it, and not an extravagant one. We do not propose to give you sensational dividends, but a steady dividend, and not to have to go back to 3 or 4 per cent. Looking at the accounts, you may think, probably, that the amount put to depreciation for buildings is a small one—only £160—but we have kept the buildings in thorough repair; they are just as good for the purpose of this Company as they were when they were erected, and we think there is quite sufficient written off, though I may say that under this head, since the commencement of the Company, there has been £2,000 written off. With regard to the mains, some gentlemen, who ought to know better, seem to think that electricity passing through them has the effect of depreciating the copper, but as a matter of fact the mains are practically immortal. The copper always maintains its value as copper, and though repairs are necessary to the covering of the mains, the amount we have written off for depreciation quite covers the repairs to be done each year, and I think the sum we have written off for mains and machinery—£3,868—is really quite enough for that purpose. We propose, with your consent, to pay an interim dividend. There is no reason why we should keep it till this time next year, and probably we shall pay it about September in each year. Then we come to the question of expenditure on capital account—what we propose to do to meet the proposed extension and to obtain the money we want for improvements. We are in such a condition now that it is absolutely necessary, with the demands made upon us by the public, which demands under penalty we are obliged to satisfy, that we should have additional mains, additional machinery, and more powerful engines. and larger dynamos. During last year our expenditure on capital account was £34,786, and was made up of three great items. First, as to the additional mains in our extended area. We have gone on in the direction of Abercromby-square as far as Prince's Park, and up to Falkner-square and London-road. We have spent this money in additional mains for that area, and replacing some small engines by more powerful ones, and in building a new station at Lark-lane. I think the expenditure has been justified; we were obliged to incur this, and we shall be obliged to incur more. We are looking forward, as you see by the report, to raising a further sum of £100,000; but we do not intend to raise it all at once, and the amount we shall raise will be ample with the uncalled money we have to last us for three or four years, as far as we can tell. We do not call up this £100,000 all at once, but we intend to issue 5,000 shares, which will bring in £25,000 which will certainly last till the end of this year. These shares we propose ts issue to our present shareholders; we propose to issue them in ordinary shares, and we shall ask for 10s. or £1 on application, and the rest in a month. Referring to the Sefton Park Station, that is a little thing in the way of an experiment, but we were very much besieged with requests from the inhabitants of Sefton Park and the neighbourhood, and so, after consideration, we secured a piece of land, built our station, and it is practically now at work. I may say that I do not think the Sefton Park Station will pay us any considerable dividend for this year, but I certainly think it will pay its working expenses, and afterwards become a very profitable station when the people have got accustomed to it. After alluding to former difficulties raised by the local authorities, which had now been overcome, the Chairman said they would be able to supply the light more cheaply when the lamp patents expired, and they were able to introduce a new lamp just invented.

The motion for the adoption of the report having been seconded, the CHAIRMAN replied to a few questions from shareholders, and called upon

Mr. A. B. HOLMES, the managing engineer, who said that the price the Company charged last year was regulated by a sliding scale, which averaged about 8d. per unit. That was the same for a large consumer as a small consumer, and the only difficulty about it was that no one understood it.

Hosted by Google

The consequence was that the time of his staff was taken up in explanations. They therefore came to the conclusion that they would adopt the simple scale of the gas company, and this, far from being a disadvantage to the consumers, had considerably reduced the Company's receipts. As far as he knew there were only two cases of people giving up the light on account of the new scale. With regard to the reduction in price, they would not be able to lessen the cost of production, but if they could get a lamp which would give them the same light at two-thirds the amount of electricity, the consumer would benefit, and the Company would have to recoup themselves in increased business. One probable source of revenue in the future was in the supply of small power. They were already supplying some people with 30 horse power, and there were others who would doubtless find that with limited space this was the best motive power they could use. Then they had 15 or 20 ventilating fans, which were giving great satisfaction, and he thought they would be able to use electricity for hoists and other work, because in all cases where the power required was intermittent, electricity could beat either steam or water.

The report and statement of accounts were then adopted, and the CHAIRMAN moved the payment of a dividend of 5 per cent. per annum, free of income-tax, and said that this would be paid in a week, which was carried.

Mr. Banner and Sir D. Radcliffe were re-elected to the directorate, and Mr. W. L. Jackson was reappointed auditor, and the remuneration of the Directors was fixed at 750 guineas.

This concluded the business of the ordinary meeting, and an extraordinary general meeting was at once formed, and the following resolutions formally agreed to :—

"*That the capital of the Company be increased to £300,000 by the addition thereto of 20,000 shares of £5 each.*"

"*That provisions of the Forged Transfers Acts, 1891 and 1892, be and are hereby adopted by and made applicable to this Company, and that compensation be made out of the funds of the Company for any loss arising from the transfer of any share or security of the Company in pursuance of a forged transfer, or of a transfer under a forged power of attorney.*"

A vote of thanks to the chairman brought the proceedings to a conclusion.

The report of the Directors referred to above was as follows :—" In presenting their tenth annual statement of accounts the Directors are glad to be able to report a steady increase in the demand for electric light, the number of lamps connected with the Company's mains on December 31, 1892, being equivalent to 20,254 16-c.p. lamps, as against 14,966 on December 31, 1891. The amount to the credit of profit and loss account is £11,421. 19s. 11d., which includes the balance brought forward from last year, and £627. 18s. 8d. received as interest on shares, paid up in advance of calls, to entitle them to rank for dividend as from January 1, 1892. The Directors recommend the payment of a dividend at the rate of 5 per cent. per annum, free of income-tax, absorbing £8,621, the addition of £1,500 to reserve fund, and to carry the balance, £1,300, forward to next year's account. The Directors propose in future, provided the results of the business continue to justify this course, to pay interim dividends about September 1st each year. The expenditure on capital account during the year, including a proportionate charge for general expenses, has been £34,786. 19s. 7d. To deal with the increase of the Company's business, the Directors ask the authority of the shareholders to increase the nominal capital of the Company by the addition of £100,000, making the total nominal capital £300,000. It is only proposed at present to issue 5,000 shares, which will be offered to the shareholders for subscription shortly after the general meeting. During the year Parliament has confirmed the Provisional Order referred to in the last annual report, under which the date for compulsory purchase of the Company's undertaking, authorised by the Provisional Order of 1889, is postponed from 21 to 42 years, the Corporation having the option of taking over the Company's supply business in the City of Liverpool, as a going concern, after December 31, 1897, at a price to be fixed by arbitration. During the year a new supply station has been established in Lark Lane for the Sefton Park district. It was intended to open this station in December last, but unexpected difficulties have arisen which have delayed the laying of the mains ; it is, however, anticipated that these difficulties will shortly be satisfactorily settled."

Birmingham Electric Supply Company (Limited).

The following is the report of the Directors to be submitted to the shareholders at the ordinary general meeting of the Company, to be held at the offices, 14, Dale End, Birmingham, on Thursday next, March 9th, at twelve o'clock :—

The amount of net profit, including the balance of £361. 19s. 9d, carried forward last year, is £3,850. 2s. 7d, ; out of this the Directors recommend the payment of a dividend of 3½ per cent., absorbing £2,056. 11s. 11d., placing £1,279. 9s. to the credit of depreciation-reserve fund, and a further sum of £250 towards a general reserve fund, and carrying forward the balance £264. 1s. 8d. to next year's account. The capital expenditure during the year amounts to £9,868. 3s. 2d., and includes the complete equipment of the present boiler house by the addition of three new boilers, the provision of two further engines and dynamos, and the extension of the Company's services.

The total number of 16-c.p. lamps, or their equivalent, on order on December 31, 1891, was 5,480, and on the same date in 1892 the number was 8,329. The demand for the light still continues to increase, and the additions since the close of the financial year bring the total number up to 9,142.

Your Directors are pleased to be able to report that since the last meeting the balance of shares alluded to in last report has been issued, the cost of such issue, £184. 12s., being added to preliminary expenses.

The frequent application for the light outside the Company's area induced the Board last year to look in what direction it might be advisable to extend the Company's system, and after careful consideration it was resolved to take the preliminary steps necessary to obtain Parliamentary powers over the district of Edgbaston, and what is known as the Jewellers' Quarter. Accordingly a deputation of the Board approached the Corporation in order to obtain their assent to these extensions. For reasons, however, with which your Board did not agree, the Corporation desired that the application should be postponed for a year ; but having regard to the uniformly courteous consideration extended by the Corporation and its officials to the Company, it was decided not then to press the matter. Your Board, however, feel that the claims of the public and interest of the shareholders alike demand that the question should not be further delayed, and at the proper time steps necessary to renew the application during the current year will be taken.

Two Directors, Mr. Geo. S. Albright and Mr. F. W. V. Mitchell, retire, and being eligible offer themselves for re-election. The auditors, Messrs. Sharp, Parsons, and Co., also retire, and being eligible offer themselves for re-election.

NEW COMPANIES, STATUTORY RETURNS, &c.

[*In addition to the information given under this heading, detailed particulars of many of the Companies whose returns appear below will be found in* "THE ELECTRICIAN" ELECTRICAL TRADES' DIRECTORY AND HANDBOOK, 1893, pages 320-348, *&c., &c.*]

BIRMINGHAM STAMPING COMPANY (LIMITED).—This Company has been registered with a capital of £9,000 in £1 shares, to carry on the business of metal stampers, press tool makers, art metal workers, &c., at Pentonville-road, London, N.

COMMELIN ET CIE.—A Company with this title has been formed in France, with offices and works at Argenteuil, for the purpose of supplying electric light and power in that town, and for exploiting a new cadmium accumulator and a new electric meter. The capital of the Company is 450,000 francs.

COMPAGNIE FRANCAISE DU BI-METAL.—A Company with this title has been formed at Paris to take over from a Company in liquidation the patent rights granted to E. Martin for bi-metallic wires and the works for their manufacture. The capital is 1,300,000 francs.

DAFEN TIN-PLATE COMPANY (LIMITED).—This Company has been registered with a capital of £25,000 in £50 shares, to manufacture and deal in iron, steel, tin, terne and black plates, and to carry on the business of smelters, steel converters, suppliers of electricity, chemical manufacturers, &c.

LILLY AND LILLY (LIMITED).—This Company has been registered, with a capital of £10,000 in £20 shares, to carry on the business (*inter alia*) of electrical engineers and contractors.

LONDON AND LANCASHIRE ELECTRIC AND GENERAL ENGINEERING COMPANY (LIMITED).—This Company was registered on February 27th, with a capital of £20,000 in £5 shares, The objects are to take over the business of electrical engineers now carried on by William Robert Pryke and William Palmer, together with any patents, licenses, trade secrets, &c., to contract for public and private lighting by electricity, magnetism, or other agency, to supply electricity and magnetism, for the production or transmission of power for locomotive or other other purposes, and to carry on the business of electricians, mechanical and electrical engineers, suppliers of electricity for the purposes of light, heat, motive power, or otherwise, and of manufacturers of and dealers in all apparatus and things required for or capable of being used in connection with the generation, distribution, supply, accumulation, and utilisation of electricity. The subscribers, with one share each, are :—William R. Pryke, William Palmer, Frederick J. Hodgson, J. Cameron Walker, William E. C. Pinchbeck, Francis A. Franklyn, and John A. Hadley.

MAZARRON ELECTRIC LIGHT COMPANY (LIMITED).—This Company was registered on February 27th, with a capital of £15,000, in 10 000 ordinary shares of £1 each and 500 £8 per Cent. Cumulative Preference shares of £10 each. The objects are to establish electric lighting in the town of Mazarron in the Province of Murcia, Spain, or elsewhere ; to acquire a concession, dated September 6th last, granted to Mr. Santiago Olivera y Bazterrica, of Mazarron ; to produce electricity and electric power ; to store, distribute, and supply light or power generated by electricity ; and to carry on the business of electricians, electrical and mechanical engineers, suppliers of electricity for the purposes of light, heat, motive power, or otherwise, and manufacturers of, and dealers in, all apparatus and things required for, or capable of being used in connection with, the generation, distribution, supply, accumulation, or employment of electricity. The first Directors are Walter B. Kingsford and Stanley W. Richard.

G. T. TONKS AND CO. (LIMITED).—This Company was registered on February 22nd, 1893, with a capital of £2,000, in £1 shares, to acquire, take over as a going concern and carry on the business of a brass founder, gas

Hosted by Google

and electric light fittings manufacturer and general metal works, carried on by George T. Tonks, Rea-street, Birmingham.

AUTOMATIC ELECTRIC RAILWAY SIGNAL COMPANY (LIMITED).—By recent agreements the above-named Company acquired from Reginald B. Annesley, George R. Leyland, Walter Emmott, and Robert W. Brown, certain patents for automatic electric railway signalling recently belonging to the Automatic Electric Railway Signalling Company (Limited) now in liquidation, the patents being granted for Great Britain and Ireland, Argentine Republic, New Zealand, Victoria, South Australia, India, and New South Wales, also certain signalling apparatus now on the premises of the Freshwater, Yarmouth and Newport Railway Company in the Isle of Wight, and other plant, for £3,400, payable £100 in cash and £3,300 by the allotment of 3,300 fully paid shares of £1 each.

BLAKEY, EMMOTT AND CO. (LIMITED).—At a meeting of this Company, held at Leeds on the 23rd ult., it was resolved that the Company be voluntarily wound up, and that Mr. James Lakeman, of 30, St. Swithin's-lane, London, E.C., and Bond-street, Leeds, was appointed liquidator.

COUNTY OF LONDON ELECTRIC LIGHTING COMPANY (LIMITED).—The annual return of this Company, made up to November 28th, has been filed; 200 shares out of a total of £100,000 in £5 shares have been taken up. £2 per share called, and all calls (£400) paid.

DIRECT UNITED STATES CABLE COMPANY (LIMITED).—The annual return of the above-named Company, made up to February 10, 1893, has been filed. Out of a nominal capital of £1,300,000, divided into 65,000 shares of £20 each, 60,710 shares have been taken up; all fully paid.

ELECTRIC WELDING COMPANY (LIMITED).—The annual return of this Company, made up to January 3rd, has been filed. The Company was registered on May 1, 1890, with a capital of £460,000, divided into 45,000 ordinary and 1,000 founders' shares of £10 each. By agreements with the Thomson European Electric Welding Company of Boston, U.S.A., and the Thomson Electric Welding Company of Boston, U.S.A., this Company acquired the British patents and the machinery, designs, &c., of the Boston companies for £212,000, payable £128,670 in cash, and the remaining £83,330 by the allotment of 8,333 fully-paid ordinary shares. At the time of making up 25,000 ordinary and 947 founders' shares were taken up, of which 8,333 ordinary shares were issued as fully paid. Upon the remaining 16,667 ordinary shares a call of £6 per share has been made, while the full amount has been called on each of the founders' shares. The calls received amount to £114,934, and those unpaid are estimated at £61,206, which includes the amount on the ordinary shares as yet uncalled. 1,960 ordinary and 365 founders' shares are held by the City of London Contract Corporation (Limited).

EPSTEIN ELECTRIC ACCUMULATOR COMPANY (LIMITED). — The annual return of this Company made up to January 6th has been filed. Out of a nominal capital of £101,000 divided into 1,000 founders' and 100,000 ordinary shares of £1 each. All the founders' and 70,207 ordinary shares have been taken up. Of these shares the founders' and 70,009 ordinary shares have been issued as fully-paid, while 5s. per share has been called and paid on the remaining 200 ordinary shares.

EUROPEAN SIMS-EDISON ELECTRICAL TORPEDO COMPANY (LT'D.).—The annual return of this Company, made up to January 5th, has been filed. The nominal capital is £201,000, divided into 10,000 ordinary shares of £20 each, and 1,000 founders' shares of £1 each; 7,880 ordinary and 849 founders' shares have been taken up, and 7,350 ordinary shares have been issued as fully paid. Upon the remaining 530 ordinary shares and the founders' shares the full amounts have been called, resulting in the payment of £9,909, and leaving £1,542 in arrears.

GULCHER (NEW) ELECTRIC LIGHT AND POWER COMPANY (LIMITED).—The annual return of this Company, made up to January 5th, has been filed. The nominal capital is £70,000, divided into 20,000 ordinary and 50,000 preference shares of £1 each, and at the time of making up, all the shares were taken up, the ordinary shares being issued as fully paid. Upon 12,277 preference the full amount has been called, while upon the remaining 37,723 preference shares 15s. per share has been called. The calls paid amount to £43,344. 1s. 4d. (which includes certain sums paid in advance of calls), while £1,057. 10s. is, as yet, unpaid.

CITY NOTES, &c.

CITY AND SOUTH LONDON RAILWAY COMPANY (LIMITED).—The traffic receipts for the week ended February 26th were £943, as against £834 for the corresponding period of last year, being an increase of £109. The total receipts for half-year amount to £7,743, against £6,739 in the corresponding period of 1892, being an increase of £1,004.

COMPAGNIE HYDRO-ELECTRIQUE (ANTWERP).—M. Mourlon has been appointed manager of this Company in the place of the late M. Van Rysselberghe.

CROYDON TRAMWAYS COMPANY.—At the ordinary general meeting of this Company, which was held on the 23rd ult., Mr. W. J. Carruthers-Wain (the Chairman) said that the Directors continued to receive a variety of offers with regard to the putting upon the Company's line of various sorts of mechanical traction, electrical and otherwise. The line was very favourably situated for demonstrations of that kind, but the Board were not going to allow their lines to be experimented upon without making agreements which should, at any rate, be in their favour.

CUBA SUBMARINE TELEGRAPH COMPANY (LIMITED).—The estimated traffic receipts of this Company for the month of February were £3,700, as compared with £3,643 in the corresponding month of last year.

EASTERN TELEGRAPH COMPANY (LIMITED).—The traffic receipts of this Company for the month of February amounted to £55,281 and to £58,284 in the corresponding period of 1892.

EASTERN EXTENSION, AUSTRALASIA AND CHINA TELEGRAPH COMPANY (LIMITED).—The traffic receipts of this Company for the month of February, 1893, amounted to £39,533, and to £39,002 in the corresponding period of 1892, or an increase of £531.

ELMORE'S FRENCH COPPER DEPOSITING COMPANY (LIMITED).—Sir Thomas Farrer, Mr. W. Saunders, M.P., and Mr. Samuel Storey, M.P., have addressed a circular to the shareholders in this Company, in which they state that the pressing applications they, in common with other shareholders, have received for assistance point to the urgent necessity for an immediate, impartial, and independent examination into the financial position of the Company. To make the inquiry effective, expert assistance would be necessary, and they think if an accountant and an electrician were appointed to assist them they would, in a few days, probably obtain all the information required. If the proposal for this investigation is favourably received, a meeting of the shareholders will be held, at which all shareholders agreeing to the proposal must either personally or by representative attend. To defray the cost of the meeting and other expenses a contribution of one penny per share is to be levied, and the whole expense is limited to £100. Mr. J. A. Robertson, C.A., of the firm of Messrs. Good, Son, and Co., 57, Moorgate-street, E.C., and Mr. A. Le Neve Foster, electrical engineer, of 61, Cadogan-square, S.W., are the gentlemen whom it is suggested to appoint, and who will proceed to Dives to examine the Company's works and report upon their capacity and upon the cost of production of the Elmore specialities. The circular further states that Major Jones (the present Chairman of the Company) and Mr. F. L. Rawson have agreed, on behalf of the Board of Directors, to facilitate the inquiry. Mr. W. J. Burnside, of 171, Queen Victoria-street, E.C., acts as secretary in the matter.

GENERAL HYDRAULIC POWER COMPANY (LIMITED).—Speaking at the annual meeting of this Company, on Wednesday, Mr. Henry Chapman, C.E., said: I dare say many of you have considered a powerful competitor in the shape of electricity. It has not affected us much. We still find that, compared with steam, compressed air, and even electricity, we compete with the best and safest power yet known for lifting, pressing, elevators, cranes, and all intermittent power. We cannot say we have arrived at finality, but I believe we are within measurable distance of supplying electricity through our power—that is to say, of using hydraulic power for driving dynamos. It is all a question of finding an economical motor. A company in Antwerp has been formed, and has obtained a concession for supplying the electric light to that city, driving the dynamos by high pressure hydraulic power—the same as ours. We therefore, rather hope we shall be able to do the same here, and we are now giving the matter our most serious attention. We shall start on a small scale. We have had one machine working satisfactorily for some years, and we shall extend it now if we can see our way to do so profitably to the Company.

GREAT NORTHERN TELEGRAPH COMPANY.—A list is issued of the drawing of 100 debentures (1883 series "B") of £100 each, which will be paid off by Messrs. C. J. Hambro and Son, 70, Old Broad-street, E.C., on presentation. Interest on these bonds has ceased.

KESWICK ELECTRIC LIGHT COMPANY (LIMITED).—The annual report of the Directors of this Company has been issued, and the Directors recommend a dividend of 2 per cent. A new boiler and apparatus has been provided for the station, which accounts for an increase in working expenses amounting to £966. During the year an additional 150 lights have been added to the Company's supply.

LIBIOLA COPPER COMPANY.—At the meeting of this Company on Monday last Mr. K. H. James, the chairman, in the course of his remarks, alluded to the immense increase in the use of copper in the United States, and attributed this to the enormous development that has taken place in electric lighting in that country. In 1890 only 85,000 tons of copper had been consumed, whereas in 1892 118,500 tons had been used in the United States, which represented about two-fifths of the entire copper production of the world. Doubtless America had arrived at the turning point in her copper production, which had increased in the past ten years from 41,000 tons to 150,000 tons, whereas the supply of copper from all other countries was practically stationary. He anticipated that the price of copper during the current year was practically fixed, and that but trifling fluctuations would be witnessed.

SANITAS COMPANY (LIMITED).—The sixteenth ordinary general meeting of this Company was held on Tuesday last, under the presidency of Mr. F. N. L. R. Moll. The Chairman announced that the sales effected during the past year showed the very satisfactory increase of 28 per cent. over 1891, resulting a credit to revenue (after deducting income-tax and adding the amount brought forward) of £10,056. 7s. 6d. An addition was made to the reserve fund of 2½ per cent. on the paid-up capital, and a dividend making, with an interim, a total distribution of 15 per cent. for the year.

SOCIETE PIEMONTAISE D'ELECTRICITE.—This Company was formed in 1890 for the purpose of taking over from the Società Generale par l'Illuminazione di Roma the electric light central station at Turin. These works cost 2,700,000 lire to erect and equip, and were acquired by the Turin

Hosted by Google

Company for 1,850,000 lire. That the change of ownership has been successful is shown by the results of the last four years' workings, the balance-sheet for 1889 showing a loss of 11,269 lire, whilst those for 1890, 1891, and 1892 show profits respectively of 52,985, 103,000, and 122,189 lire.

WESTERN AND BRAZILIAN TELEGRAPH COMPANY (LIMITED).—The traffic receipts for the week ended February 24, 1893, after deducting 17 per cent. of the gross receipts payable to the London Platino-Brazilian Telegraph Company (Limited), were £3,232.

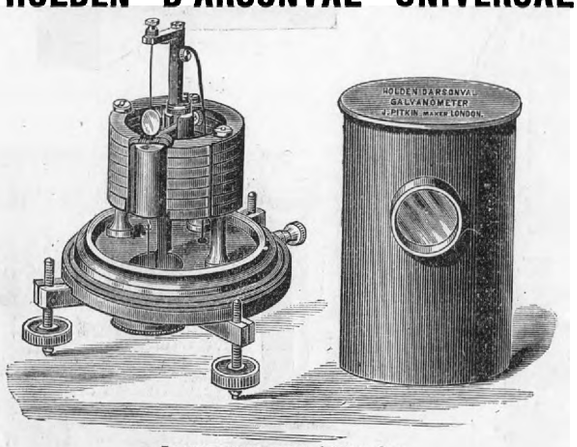
HOLDEN D'ARSONVAL UNIVERSAL DEAD BEAT REFLECTING GALVANOMETER.



INSTRUMENT WITH COVER OFF.

As supplied complete with Three Coils, Shunts, Resistances, and Self-locking Key, it is

The Best Galvanometer for Zero Testing.
The Best Galvanometer for Direct Measurements.
The Best Galvanometer for Measuring Large or Small Currents by the Shunt Method, from 1 to 1,000 Amperes.
The Best Galvanometer for Measuring E.M.F. from ·001 to 100 Volts.

Prof. W. AYRTON, Pres. I.E.E., speaking at the Institution on 26th Nov., 1891, said :—"*The deflection is larger than we have obtained with any other D'Arsonval of anything like the same size. . . . . Many times as sensitive as the Carpentier pattern for the same periodic time and resistance of coil. . . . . The method of construction has the great convenience that the coil, with its top and bottom supports, can be at once bodily withdrawn. . . . . .*"

As supplied to H.M. Govt.; The Central Institution; City Guilds; Electrical School, Chatham; R.A. College; Yorkshire College, &c.; and to Prof. Ayrton, F.R.S.; Prof. Fleming, F.R.S.; Sir T. Bazley, Mr. J. W. Swan, and many others.

Circulars, with all information, from the SOLE MANUFACTURER,

Mr. J. PITKIN, 56, RED LION STREET, CLERKENWELL, E.C.

Maker of Capt. HOLDEN'S CHRONOGRAPHS, FIRING KEYS & ELECTRICAL MEASURING INSTRUMENTS, particulars of which will be sent on application.

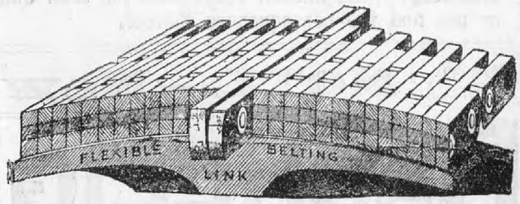
ORANGE TAN LEATHER offers the following ADVANTAGES:—

It possesses **more life** than any other Belt in the market.
It is **stretchless** and takes a **splendid grip** of the pulley.
It can carry with ease **one-third more load** than other leather.
It is **very thin** and **pliable**, and for **small diameters, fast speeds, and heavy work**, no other leather can compare with it.
Breaking strain (Lloyd's Proving House): **Orange Tan, 8,244lbs. Oak Tan, 5,746lbs.** per square inch.



17 HIGHEST AWARDS AT INTERNATIONAL EXHIBITIONS.

Where the one pulley is **flat** and the other **round**, this Belt will **easily accommodate itself** to either pulley, while at same time it will transmit the **maximum power.**

MOST TRUSTWORTHY BELT for ELECTRIC DRIVING.

We beg to call attention of belt users to a perusal of our Illustrated **GUIDE TO BELT-DRIVING,** *which we will send gratis on demand.*

SALES BY AUCTION, &c.

ROYAL GALVANIC BATHS, 55, Marylebone-road, N.W.

SALE OF HOUSEHOLD FURNITURE, COPPER BATHS, ELECTRIC INSTRUMENTS, &c.

MESSRS. GEORGE HEAD and CO. will SELL BY AUCTION, on the Premises, as above, on WEDNESDAY, March 15th, 1893, at 2 o'clock, the HOUSEHOLD FURNITURE and Effects, comprising the usual bed room appointments, couches, easy chairs, mahogany and other tables, chimney and pier glasses, cheval glasses, fenders, carpets, china, and kitchen utensils; also copper and other baths, a number of specially made electric bath coils, electrodes, batteries, indicators, &c., a galvanometer and Wheatstone bridge coils by Latimer Clark, Muirhead and Co., a quantity of iron piping, fittings for shower, needle, and douche baths, insulated wiring, &c.

May be viewed the day prior to the Sale, and catalogues obtained on the premises, or at the Auctioneers' Offices, 7, Upper Baker-street, N.W.

MOODIE'S GOLD MINING AND EXPLORATION COMPANY (LIMITED).

TRANSMISSION OF ELECTRICAL POWER.

TO CONTRACTORS.

TENDERS are invited for the SUPPLY and ERECTION, upon the Company's Estate, near Barberton, South African Republic, of certain MACHINERY, PLANT, &c., for the purpose of

GENERATING and TRANSMITTING 250-H.P. by Electricity to various Sub-companies.

Specification and Conditions of Contract, &c., can be obtained from, and Plans seen, at the following places:—

OFFICES OF THE COMPANY:

Pietermaritzburg, Natal;
Moodie's near Barberton, South African Republic;
No. 8, Old Jewry, London, E.C.;

and at

Johannesburg (Messrs. Redwood and Watson), P.O. Box, 500;
Capetown (E. R. Syfret, Esq.), 39, St. George's-street;
America: Messrs. Corner Bros. and Co., New York, in conjunction with their Boston Agents.

Tenders, together with Specification and Conditions of Contract, &c., duly signed, attached thereto, must be sent in to the Head Office of the Company, Pietermaritzburg, Natal, by Noon on the 3rd day of MAY, 1893, and a Duplicate Copy must be lodged with the London Office, 8, Old Jewry, E.C., by the same time.

A Fee of Three Guineas will be charged for Copies of Specification, Conditions of Contract, &c., and inspection of Plans, which will be returned on receipt of a bona fide Tender.

The Lowest or any Tender not necessarily accepted.

By Order of the Board of Directors,
C. J. MACFARLANE, Secretary.
Moodie's Gold Mining and Exploration Co. (Limited).

Pietermaritzburg, Natal,
January, 1893.

BOROUGH OF DEWSBURY.

ELECTRICITY.

AMENDED ADVERTISEMENT EXTENDING TIME FOR SENDING IN TENDERS.

The CORPORATION invite TENDERS for the CONSTRUCTION, SUPPLY, and LAYING DOWN of the necessary PLANT and MAINS for the SUPPLY of ELECTRICITY in the Borough, in accordance with the specification, plan, and form of tender, which can be obtained from the undersigned on payment of £2. 2s., which will be returned on receipt of a bona fide tender.

The person or firm whose tender is accepted will be required to enter into a contract and a Bond with two approved sureties for the due performance of the contract. Sealed tenders, endorsed "Electricity," to be delivered at this office not later than SATURDAY, the 8th April, 1893.

Firms tendering may tender for the whole or any part of the Plant.

The Corporation do not bind themselves to accept the lowest or any tender.

By order,
E. MAWDESLEY, Town Clerk.

Town Clerk's Office, Town Hall,
Dewsbury, 9th March, 1893.

WHITEHAVEN ELECTRIC LIGHTING ORDER, 1891.

TO ELECTRIC LIGHTING CONTRACTORS.

The TRUSTEES of the TOWN and HARBOUR of WHITEHAVEN invite TENDERS for SUPPLYING and LAYING INSULATED CONDUCTORS required in connection with their Central Electric Lighting Station.

Plans can be seen, and a Copy of the Specification and Forms of Agreement and Tender obtained, at the Office of Dr. John Hopkinson, F.R.S., 5, Victoria-street, Westminster, S.W., and also at this Office, on payment of One Guinea, which will be returned if a bona fide Tender is sent in and not accepted.

Sealed Tenders, addressed to the undersigned, and endorsed "Tender for Electrical Conductors," must be delivered not later than 10 a.m. on WEDNESDAY, 22nd March instant.

The Trustees do not bind themselves to accept the lowest or any Tender.

By order,
JOHN COLLINS, Secretary.

Town Hall, Whitehaven, March 2nd, 1893.

BRAZILIAN SUBMARINE TELEGRAPH COMPANY (Limited).

NOTICE is Hereby Given that the TRANSFER BOOKS of this Company will be CLOSED from SATURDAY, 18th, to FRIDAY, 24th inst., both days inclusive, preparatory to paying an Interim Dividend of 3s. per share, or at the rate of 6 per cent. per annum, free of income-tax, for the quarter ended December 31st, 1892, and payable on the 25th inst.

By order,
RICHARD COLLETT, Secretary.

THE ELECTRICIAN:

A WEEKLY ILLUSTRATED JOURNAL OF

ELECTRICAL ENGINEERING, INDUSTRY AND SCIENCE.

No. 773 —Vol. XXX. FRIDAY, MARCH 10, 1893. PRICE FOURPENCE.
Annual Subscription (U. K.), 19/6

NOTES.

The *Electrical Review* and *Science Siftings* Defence Fund has received a handsome contribution of £1,000 from Mr. C. B. Harness, not perhaps spontaneous, but due to the suggestion of a special jury and the approval of Lord Chief Justice Coleridge. While further congratulating our contemporary on having for the third time completely discomfited what Mr. Finlay called "an abominable system of imposture," we regret that Mr. Harness's plea that he was "not prepared to meet the case" should have stopped the mass of evidence which had been prepared, and which Lord Coleridge ruled to be relevant to the issue. We will believe in the other action which is said to be pending when it is brought into Court.

The discussion which took place last week at the Société Internationale des Électriciens on the American proposals with regard to electrical units was eminently satisfactory, in that there was no flood of new names or new units. We might well expect nice distinctions, and, where M. Hospitalier is to be found, accurate ones. We humbly note that M. Blondel thinks that "voltage" is slang, and accept his opinion. It might be argued that when a word is lifted bodily from the French language into the English, or *vice versâ*, it is rather difficult to determine whether it remains or becomes slang or *argot*, as the case may be. The modern French verb *five-o'cloquer*, for instance, is, we believe, *barbare* rather than *argot*, but, in the present instance, we have a guilty feeling that "voltage" was slang in its native country before it was imported into France. But what of it? True, we used the expressions "slovenly," "slang," and "far worse," in connection with "potential," "P.D.," and "E.M.F." a few weeks ago, tacitly approving of "voltage" in the same Note. We are inclined to agree with M. Blondel, Mr. Swinburne, and others who object to "voltage," but, all the same, we prefer it to most of its synonyms. We use C^2R without a scruple, but it is as bad as E.M.F. as far as its slanginess goes; as an adjective, *e.g.*, "C^2R losses," it has no synonym but the uncouth "joulian."

It is for scientific accuracy of terminology that we look to our French friends, rather than for verbal renderings of terms. We should not quarrel with them if they chose to speak of "*l'exploitation de l'installation d'une canalisation*," but regret to see these words imported with but little reason into ordinary English language. M. Guillaume's distinction between "resistance" and "resistibility" is rather too nice. Who would have time to remember which was which? There is, of course, a difference in the two uses which he proposes to make of them, but it seems hardly worth while to keep up the distinction at the expense of two names. The opinion of the society on the "henry" would have been interesting; this stands a better chance of adoption than the "gauss," "weber," "gilbert," and "œrsted," if only because of the numerous proposed denotations of the "gauss" and the "weber," and the comparative novelty of the "gilbert" and the "œrsted."

The radical abolition of the expression "bougie-metre" is only what one expects from M. Hospitalier, and as "lux" has been proposed, there is at all events no need to mangle any classically derived words, as is the custom of electrical logodædaly. The real objection to the "bougie-metre" or to the "candle-foot" arises when an illumination is expressed as a number of such units. The objectors say that 3 candle-feet implies the product of 3×1 candle $\times 1$ foot. The advocates say it simply means three times the unit of illumination, viz., 1 candle-foot; they imply nothing, and if anybody is so ignorant of optics as to suppose they mean 3×1 candle $\times 1$ foot, it is no business of theirs. Let the candle remain at 1 foot, or the bougie at 1 metre, and let the numeric in any given case simply denote a multiplier or divisor of that unit.

The closing of the Hanover Square School of Electrical Engineering and Submarine Telegraphy is not only in itself regrettable, but it is a significant sign of the times. Private enterprise seems destined in an ever-growing degree to be superseded by State or Municipal subsidised ventures, and this tendency, ever present in educational matters, is carrying all before it in this era of technical education. When the Hanover Square School first came into existence "sons of gentlemen" were possibly wanted to fill high appointments in the then restricted field of applied electricity, but it was a pity that such an invitation to increase the rush into the electrical profession should have been continued long after this state of things ceased to exist.

The tendency to ask for more is never more pronounced than when dividends are concerned. On this account, therefore, it is perhaps to be regretted that the companies who

Hosted by Google

have the cream of the electricity supply business in their hands should have been the first to hold their annual meetings. A more artistic effect would have resulted had the dividends successively declared gradually risen from zero to a maximum instead of taking a sharp dip from 7¼ per cent. down to nothing.

On Thursday, last week, the Directors of the House-to-House Company met their shareholders at the West Brompton Central Station. The chief item of technical interest that transpired was the announcement that the House-to-House Company has fallen into line with the prevailing fashion, and has in contemplation the adoption of the transformer sub-station system of distribution. To the shareholders, however, the most comprehensible and, in their opinion, no doubt, the most reprehensible fact, was the absence of dividend.

At first glance if one is without any *a priori* convictions in regard to continuous and alternate currents, it is somewhat puzzling, lookely solely at the accounts, to understand why the Kensington and Knightsbridge Company should manage to scrape together the wherewithal to pay a modest dividend, whilst the House-to-House Company close by should be unable to perform a similar feat. The total capital expenditure up to December 31, 1892, amounted in the case of the Kensington Company to £153,000 in round figures, the lamps numbering 47,441 and the capital outlay per lamp connected being £3. 4s. For the House-to-House Company these figures are respectively £70,000, 23,700 and £2. 19s. The electricity revenue per lamp connected is in the case of the Kensington Company 7s. 1d., in that of the House-to-House Company 8s. 1d. So far what little difference there is, is in favour of the House-to-House Company. On turning to the "sheer cost" of production, however, the solution of the problem is writ very fine and large. The Kensington Company's expenses under that heading come to £3,746; in the case of the House-to-House Company they are £5,604.

The cable phenomena described by Herr Neustadt in another column are of interest in connection with high pressure systems of distribution by means of alternating currents. The combined action of condensers and inductive circuits produces the same effect as a transformer in changing the pressure of the circuits connected with them; and the resulting increase of voltage may in some cases become serious. An effect of this kind, as is well known, was noticed two years ago on the Deptford mains, but its importance was small, as it practically disappeared when the mains were conveying power, and in no case was the rise of voltage great enough to endanger the insulation of the cable. The result might, however, have been far more serious as the phenomenon was new and altogether unexpected. In some cases referred to by Herr Neustadt serious damage to the cables resulted from a cause of this nature, and it thus becomes of evident importance in such systems of distribution that proper precautions should be taken to guard against breakdowns. As Herr Neustadt points out, it is always easy to avoid any such danger.

The article will be read with more general interest owing to the omission of the mathematical theory, the result of the investigation being summarised in three formulæ. These expressions, it must be confessed, are somewhat lengthy, but their meaning is rendered easily intelligible by giving the numerical details of an actual case. Whether the example chosen is a practical one of course depends upon the data assumed, but for the most part these will be regarded as likely values for an actual system of mains. With regard, however, to capacity, it appears excessive to assume 50 microfarads for a cable only 80 kilometres long, and although a current-frequency of 43 periods per second is common enough in Germany, it does not at all represent English or American practice.

The result of the experiments which have been made as to the use of glow lamps with green side lights for ships, is unexpected, and it is not easy to account for them. Capt. Abney and others have found that the light of a glow lamp is practically the same as that of a good gas flame, and the only clue to the explanation seems to be that the oil flame of an ordinary ship's light differs materially in quality from a gas flame. It might have been expected that "electric light of very considerable candle-power" would have been, if anything, rather whiter than an oil lamp. If so, its spectrum, extending farther towards the blue, should be richer in green rays; but for some reason the colour was too pale. The brilliancy of the light, that is, the quantity apart from the quality, ought not to alter the colour.

Royal Society.—Amongst the Papers down for reading yesterday was one by Prof. J. J. Thomson, on "The Electrolysis of Steam."

The Commercial Cable Company.—The Directors of the Commercial Cable Company have decided to forthwith lay a third cable between Nova Scotia and Ireland.

The British Association, 1894.—*The Times* has reason to believe that Lord Salisbury has accepted the Presidency of the British Association for the year 1894, when the meeting will be held at Oxford.

Lang v. the House-to-House Electric Lighting Company.—It should have been stated in our report of this action last week that in the event of a verdict for the plaintiff the damages had been agreed at £195.

The Western Union Telegraph Co.—According to telegraphic advice received yesterday, General Eckert has been elected (in place of the late Dr. Norvin Green) President of the Company, retaining the position of General Manager.

Accrington.—A Local Government Board inquiry was held at Accrington on Wednesday last week relative to the application of the Town Council for sanction to borrow £22,000 for various purposes, including the erection of an electric lighting station.

A Chair of Electricity.—A decree has been issued by the Minister of Public Works creating a Chair of Electricity at the École Supérieure des Mines. M. Blondel, well known for his work in connection with alternate current working, is a candidate for the post.

Derby.—On Thursday last week Mr. F. H. Tullock, an inspector appointed by the Local Government Board, held an inquiry at Derby into the application made by the Corporation for sanction to borrow £50,600 for various purposes, of which £30,000 was for the inauguration of the electric light.

Hosted by Google

Ealing.—At the meeting of the Local Board on Thursday last week, the Chairman moved that the Board request Messrs. Bramwell and Harris to prepare plans and specifications for the execution of the electric lighting scheme detailed and recommended in their report. The motion was carried unanimously.

Cable Repairs and Interruptions:—

Cable Repaired.	Interrupted.	Repaired.
St. Thome-Loanda	February 17, 1893 ...	March 6, 1893.

Cables actually interrupted.

Cayenne-Vizeu	September 24, 1892.
Gibraltar-Tangier	February 18, 1893.

The Post Office and the Telephones.—Amongst the Select Committees of the House of Commons asked for, is one to consider the proposed arrangements between the Post Office and the telephone companies, and generally as to the future policy of the Post Office with reference to the extension of the telephone service.

Vienna.—An interesting station has been erected here by Ganz and Co., who utilise the water of the Iser to drive, by means of turbines, two 50-H.P. dynamos for lighting certain factories, and two 65-H.P. dynamos for supplying them with power. The former are alternate-current 1,800 volt, and the latter direct-current 550 volt machines. The distance of the transmission is about a mile.

Indian Telegraphs.—The Telegraph Department is, says the *Indian Engineer*, likely to show good results for the current financial year. There will also appear a very large increase in the number of new offices opened. We are, says our contemporary, probably within measurable distance of that four-anna telegram which only three or four years ago seemed like the dream of an imaginative Director-General.

Berlin.—Some interesting statistics of the lighting of Berlin during the past year are given in the *Journal für Gasbeleuchtung*. The total quantity of gas accounted for amounts to 4,062,568,000 cubic feet, against 3,945,185,000 cubic feet in the previous year, an increase of nearly 3 per cent. On the other hand, the use of the electric light has increased nearly 30 per cent. during the same period; and the importations of petroleum have advanced 6·5 per cent.

The German Electric Lighting Bill.—The German Electric Light and Power Bill, after slumbering on the table of a committee for a year and a-half, has been rushed through the Federal Council, and is, it seems, to be similarly treated in the Imperial Diet, before which it has just been laid. The Electric Light Bill is said to be neither necessary nor useful. It is, moreover, contended that the Bill, if it become law, will seriously hamper the electrical industries.

A Proposed Metropolitan Electric Railway for Vienna.—The Anglo-Austrian Bank, in conjunction with Messrs. Siemens and Halske and the General Austrian Electricity Company, has approached the Vienna Municipality with a detailed scheme for the construction of an electric railway to encircle the inner town and a branch line to pass through the inner part of the town. If a concession is granted for these lines, they would be laid down on the slotted conduit or Budapest system.

Tunbridge Wells.—At a meeting of the Town Council last week the proposal to adopt the electric light was discussed. Alderman Clifford moved the confirmation of Mr. Preece's report. Alderman Cronk moved an amendment in favour of deferring the matter for two years. An animated debate followed; and, on a show of hands being subsequently taken, 14 voted for the amendment and 14 for the original motion. By the casting vote of the Mayor the amendment was carried.

City and South London Railway.—A slight accident occurred at half-past nine on Monday morning on this railway between the Borough and the Monument Stations. Just after the 9:20 up train from Stockwell had left the Borough the brake got out of order, the train being immediately brought to a standstill. The driver and conductor examined the engine, but, finding it impossible to proceed, one of them informed the signalman at the station and another engine was procured, the passengers being carried back to the Borough.

Old Students' Association.—A very successful *soirée* was held in connection with this Association on March 3rd at the Central Institution, when Mr. Clinton T. Dent, the well-known Alpine climber, gave a most interesting lecture on "Mountain-craft," which was illustrated by very fine lantern slides from photographs by Mr. Dent, Prof. Donkin and others. A very large and brilliant audience attended the lecture. A hearty vote of thanks was passsed to Mr. Dent for his kindness in giving the lecture, which was much applauded. The dance in connection with the Association takes place on the 17th of March.

The Recent Telephone Case.—What's in a name? we are tempted to ask, on reading the following paragraph in *Electricity* of New York with regard to Transatlantic testimony in the recent telephone case:—"The English counsel had collected a mass of evidence showing that the tramway wires did not seriously injure those of the Telephone Company. Mr. Wise advised that all this testimony was irrelevant, and that the proper position to take was to admit the serious injury, but to claim equal rights to the earth with the Telephone Company." His advice was taken, and, of course, the Court sustained Mr. Wise's contention. How could it do otherwise?

A Proposed Postal and Telegraph Consultative Committee.—Mr. Henniker Heaton intends, upon the Post Office Vote, to press upon the Government the desirability of establishing a Postal and Telegraph Consultative Committee, similar to that existing in France called "La Commission Consultative des Postes et des Télégraphes," to consist, as in France, of 26 members, selected from the members of both Houses of Parliament, presidents of chambers of commerce, chairmen of railway companies, and representatives of the principal commercial, industrial, and social bodies. The Postmaster-General to be the President of such Committee.

Long Telegraph Lines in India.—The *Indian Engineer* of February 11th states that a few days previous to that date Calcutta was connected with Madras by way of Nagpur and Bombay, and messages were transmitted duplex direct. The distance was 2,100 miles, and the wire employed was of copper. The same journal states that a new and heavier copper wire is now being laid from Calcutta, through Dohnd and Manmad, to Madras. When it is ready the service along it will be unequalled among land telegraphs in the world. The necessity for this route arises from the fact that the line along the East Coast is subject to constant interruptions, and is most difficult to maintain in working order, especially during the monsoon seasons.

Telegraphists' Grievances.—In the House of Commons on Tuesday night Mr. Dalziel asked the Postmaster-General whether he would explain why the decision of his Department with regard to the petition received on April 12th last from the senior telegraphists employed at the Central Telegraph Office, setting forth certain alleged grievances, had not yet been made known. Mr. Arnold Morley said that the petition referred to repeated a number of points on which decisions had been previously conveyed to the petitioners, and he feared that, with the exception of an addition to the number of the class of assistant superintendents, which he was glad to say had now been sanctioned by the Treasury, he was not in a position to accede to the prayer of the petition. The answer had been delayed pending the decision of the Treasury on the point mentioned.

The Electric Railway Bills.—The provision in the South-Eastern Railway Bill for an electric tramway between St. Leonards and Hythe has been abandoned.—Mr. Mundella will move the rejection of the Brighton and Rottingdean Sea Shore Electric Railway Bill on the second reading.—Every endeavour will be made to get a clause inserted in the London electric railway Bills reserving to the London County Council power to purchase the undertakings after the expiration of a limited period, on terms similar to those provided in Section 43 of the Tramways Act, 1870.—The Committee appointed to consider the City and South London Railway Bill, the Extension of Time Bill for the continuation of the line to Clapham, the Clapham Junction and Paddington, and the Edgware-road and

Hosted by Google

Victoria Railway Bills, will consist of Sir John Kennaway (Chairman), Mr. Gourley, the Marquess of Granby, and Mr. Grenfell. The Committee will hold its first sitting on Monday next.

The General Electric Company of America.—*Electricity*, of New York, is waging a vigorous campaign against the General Electric Company, which, according to it, threatens to monopolise the entire electrical business of the United States. The lamp case is, in its opinion, an important one, but not all important. Other patents are in reserve. The Electric Trust will, thinks *Electricity*, upset and demoralise the entire electric street-railway industry during the next two years. In the lighting field there will be patent suits almost without end. Suits are now being prepared claiming fundamental patents on sockets, fuses, the three-wire system and feeder distribution. The compound winding of machines is also claimed, and will be the first matter to be pushed to a finish. A truly gloomy presage, and, if correct, one which almost warrants the very strong language indulged in by *Electricity*, not only against the General Electric Company, but against its technical contemporaries who do not happen to see eye to eye with it in this matter.

A New Paris Central Station.—Our Paris correspondent writes that on Tuesday the central station supplying the Secteur des Champs-Elysées was formally "inaugurated." The station is situated at Levallois, on the borders of the Seine, a little over a mile from the fortifications. The station covers an area of 27,500 sq. ft. The feed water is taken direct from the Seine. The area of supply covers 4½ sq. miles. The plant comprises five Galloway boilers and six Corliss engines each driving direct on to a 400 kilowatt Hillairet-Huguet alternator. At 60 revolutions these alternators give 40 ∿. They have 80 coils of the Lontin type, and revolving field-magnets 19ft. in diameter, and they give 133 amperes at 3,000 volts. It is proposed to run the alternators in parallel. In the station all high-pressure wires are painted red, low-pressure wires black, whilst the conductors of the 150-volt exciting circuit are bare. Zipernowski transformers are employed. The station is fitted with a Green economiser and a Gaillet purifier.

Atmospheric Electricity.—On Wednesday next, at 7 p.m., Mr. Shelford Bidwell will deliver before the Royal Meteorological Society, at 25, Great George-street, Westminster, a lecture on "Some Meteorological Problems," which will be illustrated by experiments. The lecture will treat of the probable sources of atmospheric electricity, with experiments showing electrification produced by evaporation and by friction of dust, and the different forms assumed by the lighting flash. Photographs of flashes and electric sparks will be shown. The resemblance of a Leyden jar discharge to lightning will be demonstrated. The duration of flashes will be shown by means of a revolving disk. The efficiency of lightning conductors, Dr. Lodge's two forms of lightning discharge, the darkness of thunder clouds, the large rain drops of thunder showers, the electrification of steam jets and water jets, the influence of the dust in the air on condensation of water vapour, and the colour of the sky will be discussed.

Electric Traction at Coventry.—At the last meeting of the Coventry Town Council it was proposed that the portion of the minutes of the General Works Committee relating to the agreement with Mr. Graff Baker on the subject of the equipment of the electric tramways should be referred back. The mover said the Council on January 17th passed a resolution giving permission to Mr. Baker to introduce the Thomson-Houston system, provided that an equitable agreement could be arrived at between him and the Corporation, and the report of the General Works Committee was referred back with instructions to report as early as possible. Six weeks had now passed, and no report had been presented, but on the minutes it was stated that the Committee had considered the proposed agreement and agreed upon modifications thereof. It would be advisable to know whether the General Works Committee were carrying out the wish of the Council that electric traction should be introduced, whether the modifications were not of such a nature as to render the scheme impossible, and whether there was a danger that the scheme would actually fall through before the report was presented to the Council. A discussion ensued, in the course of which it transpired that there was no danger of the scheme falling through, and that the Committee were making every endeavour to hurry forward the completion of the negotiations. The motion was in consequence withdrawn.

American Experiences.—On Friday evening last a Paper was read at a students' meeting of the Institution of Electrical Engineers by Mr. J. M. Barr on "The American Experiences of an Embryonic Electrician." Prof. Ayrton occupied the chair. The Paper dealt in a humorous manner with many difficulties of young electricians in America, gave some useful practical information, and pointed out that students who entered the factory as ordinary workmen were often able to secure the most useful practical experience. Mr. Barr said that when he left college he found that there were three ways of acquiring practical knowledge; one was to enter the factory as a premium pupil, another was to gain admission by influence, and the third was to apply *incognito* and be taken on as an ordinary workman. On the whole he found that the last course was preferable, although it had the drawback of entailing long hours. He had without difficulty passed from department to department of the works and managed to acquire considerable information. He then proceeded to give some details of American practice, and gave an instance in his own experience where a lighting plant had to be laid down in an iron mine. The mine was a wet one, and being at a distance from any factory it was necessary to press domestic utensils into service. The wiring was carried out with bare conductors which had previously been drawn through a trough containing an insulating paint, the leads were attached to porcelain insulators fixed in the logs forming the roof of the mine. To protect these insulators from the running water, shades had to be improvised from several hundred bread pans. Mr. Barr then proceeded to explain the manufacture and testing of glow lamps and the methods of dry and wet "flashing." He also referred to the new Westinghouse lamps, the one with a glass stopper cemented in, and the other having a silicate plug with leading-in wires of iron, the composition of the plug being such that the co-efficient of expansion was the same for both the plug and the wires.

Brighton.—A Board of Trade Inquiry was held at the Brighton Town Hall, on Tuesday, by Mr. Ingram B. Walker and Major Cardew, with reference to the application of the Brighton Electric Light Company for a Provisional Order to supply electricity for public and private purposes within the Borough. Mr. Fletcher Moulton, Q.C., appeared for the Corporation; Mr. Castle, Q.C., appeared for the Company. Evidence was given on behalf of the Company at considerable length by Mr. Robert Hammond, and also by several customers, who declared themselves satisfied with its electric supply. Mr. Fletcher Moulton, passing over the history of the matter prior to 1889, stated that Parliament had from the very first taken up the position, that if the public preferred to supply themselves with such articles of consumption as gas and water, so as to relieve the burden of the ratepayer, they might decline to allow enterprises such as that of the Company to be made the subject of private property, private persons, or private companies. There was no shadow of a ground for accusing the Corporation of having failed in what they had undertaken. The Corporation had done all that a careful and responsible Municipality ought to have done. There would soon be £80,000 of the ratepayers' money invested in the Electric Light Works; nothing could more conclusively show the municipal *bona fides*. Mr. Castle said that when it had been stated that the Corporation had put forward a document containing false statements, it was strange that no attempt should have been made to justify them. He was debarred from going into the whole of the transactions before 1889, as he very much desired to do. But the real point to be kept in view was that the petitioning Company could not be turned out. If the Board of Trade refused this application, the Company must then go on with their present system, that was said not to be safe and to be prejudicial to the public. The Company had supplied a large public want, had done good work to the town, and had put £33,000 into the business. He asked the inspectors to favourably recommend this application to the Board of Trade.

ELECTROMAGNETIC THEORY.—XLV.

BY OLIVER HEAVISIDE.

(*Continued from page 474.*)

§ 189. The properties of a perfect conductor are derived from those of common conductors by examining what would happen if the resistivity were continuously reduced, and ultimately became zero. In this way we find that a perfect conductor is a perfect obstructor, for one thing, which idea is singularly at variance with popular notions regarding conductors. But it is also a perfect conductor literally, though in a different sense to that commonly understood. Ohm's law has played so important a part in the development of electrical knowledge, especially on the practical side, that it is really not at all a matter of wonder that some practicians should have been so reluctant to take in the idea of a conductor as an obstructor. Scientific men who can follow the reasoning by which the functions of conductors follow from known facts have no difficulty in pursuing the consequences far beyond experimental observation. Again, younger men, with fewer prejudices to surmount, do not find much trouble with superficial conduction and internal obstruction. But the old established practitioner with prejudices, who could not see the reason, was put into a position of some difficulty—resembling chancery. If you have got anything new, in substance or in method, and want to propagate it rapidly, you need not expect anything but hindrance from the old practitioner—especially if he sat at the feet of Faraday. Beetles could do that. Besides, the old practitioner is apt to measure the value of science by the number of dollars he thinks it is likely to bring into his pocket, and if he does not see the dollars, he is very disinclined to disturb his ancient prejudices. But only give him plenty of rope, and when the new views have become fashionably current, he may find it worth his while to adopt them, though, perhaps, in a somewhat sneaking manner, not unmixed with bluster, and make believe he knew all about it when he was a little boy! He sees a prospect of dollars in the distance, that is the reason. The perfect obstruction having failed, try the perfect conduction.

You should make your converts out of the rising generation and the coming men. Thus, passing to another matter, Prof. Tait says he cannot understand my vectors, though he can understand much harder things. But men who have no quaternionic prejudices can understand them, and do. Younger men are born into the world with more advanced ideas, on the average. There cannot be a doubt about it. If you had taught the Calculus to the ancient Britons you would not have found a man to take it in amongst the whole lot, Druids and all. Consider too, what a trouble scientific men used to have with the principle of the persistence of energy. They could not see it. But everybody sees it now. The important thing is to begin early, and train up the young stick as you want it to grow. Now with Quaternions it is different. You may put off till to-morrow what you cannot do to-day, for fear you commence the study too soon. Of course, I refer to the Hamilton-Tait system, where you have to do violence to reason by making believe that a vector is a quaternion, and that its square is negative.

According to Ohm's law alone, a perfect conductor should be one which carried an infinite current under a finite voltage, and the current would flow all through it because it does so ordinarily. But what is left out of consideration here is the manner in which the assumed steady state is established. If we take this into account, we find that there is no steady state when the resistance is zero, for the variable period is infinitely prolonged, and Ohm's law is therefore out of it, so far as the usual application goes. In a circuit of no resistance containing a finite steady impressed voltage E, the current would mount up infinitely and never stop mounting up. On the other hand, if we insert a resistance R in the former circuit of no resistance, there will be a settling to a steady state, for the current in the circuit will tend to the value E/R, in full obedience to Ohm's law. The current is the same all round the circuit, although a part thereof has no resistance. We conclude that that portion has also no voltage.

But this is only a part of the story. Although we harmonise with Ohm's law, we overlook the most interesting part. The smaller the resistance the greater the time taken for the current to get into the conductor from its boundary, where it is initiated. In the limit, with no resistance, it never gets in at all. Where, then, is the current? For, as we have said, it mounts up to a finite value if there be a finite resistance inserted along with the perfect conductor, and mounts up infinitely if there be no resistance.

We recognise the existence of electric current in a wire by the magnetic force round it, and in fact measure the current by its magnetic force. Therefore, according to this, there is the same total current in the wire, if the magnetic force outside it remains the same. If, then, the magnetic force stops completely at the surface of the wire, whose interior is entirely free from magnetic force, the measure of the current is just the same. The uniformly distributed current of the steady state appropriate to finite conductivity becomes a mere surface current when the conductivity is infinite. In one case we have a finite volume-density of current, and in the other a finite surface-density. When the current inside the wire is zero so is the electric force, in accordance with Ohm's law again. The electric and magnetic phenomena are entirely in the dielectric outside the wire, the entrance of any similar manifestations into it being perfectly obstructed by the absence of resistance. For this purpose the thinnest skin would serve equally well. In the usual sense that an electric current is a phenomenon of matter, it has become quite an abstraction, for there is no matter concerned in it. It is shut out completely. In the circuit of finite resistance, a portion of which is a wire of no resistance, supporting a steady current, there is no difference whatever in the external magnetic force outside the resisting and non-resisting parts, though in one case there is entrance of the magnetic force and waste of energy, whilst in the other there is no entrance and no waste. These conclusions do not rest upon Maxwell's theory of dielectrics, but upon the second circuital law of electromagnetism applied to conductors. But it is only by means of Maxwell's theory that we can come to a proper understanding and explanation of the functions of conductors.

The sense in which a perfect conductor is a perfect conductor in reality as well as in name is that it allows electromagnetic waves to slip along its surface in a perfectly free manner, without waste of energy. Though perfectly obstructive internally, it is perfectly conductive superficially. It merely guides the waves, and in this less technical sense of conduction the idea of a perfect conductor acquires fresh life.

§ 190. The conditions at the interface of a perfect conductor and a dielectric are that the electric force in the dielectric has no tangential component and the magnetic induction no normal component. Or

$$V\mathbf{N}\mathbf{E} = 0, \qquad \mathbf{N}\mathbf{H} = 0,$$

if $\mathbf{N}$ be the unit normal from the conductor. Thus, when there is electric force at the boundary it is entirely normal, with electrification to match; and if there is magnetic force it is entirely tangential, with electric current to match. Both electrification and current are superficial. The displacement measures the surface density σ of the one, and the magnetic force that of the other, say $\mathbf{c}$, thus

$$\sigma = \mathbf{N}\mathbf{D}, \qquad \mathbf{c} = V\mathbf{N}\mathbf{H},$$

in rational units, without any useless and arbitrary 4π constant, such as is required in the B.A. system of units, of amazing irrationality. If, then, we have electromagnetic disturbances given in a dielectric containing a perfect conductor, the latter first of all is free from disturbance, and next causes such reflected waves as to annihilate the tangentiality of the electric force and the normality of the magnetic force.

As regards steady states, the influence of a perfect conductor on induction due to foreign sources is to exclude it in the same manner as if the inductivity were made zero; that is, the induction goes round it tangentially instead of entering it. This is usually ascribed to an electric current-sheet induced upon its surface, whose internal magnetic force is the negative of that due to the external field. This is right mathematically, but is deceptive and delusive physically. There is no internal force,

Hosted by Google

neither that of the external field nor that of the superficial current. The current sheet itself merely means the abrupt stoppage of the magnetic field, and cannot really be supposed to be the source of magnetic force in a body which cannot permit its entrance. The previously mentioned case of a perfectly conducting wire inserted in a circuit of finite resistance supporting a steady current, will serve to bring out this point strongly. The supposed induced superficial current is now actually the main current in the circuit itself.

It is different with the steady state due to external electric sources. The displacement is just as much shut out from the perfect conductor (which may also be a dielectric) as was the magnetic induction, but in a strikingly different manner, terminating upon it perpendicularly, as if it entered it in the manner that would happen were the conductor nonconducting, but of exceedingly great permittivity, so that it drew in the tubes of displacement.

Although a perfect magnetic conductor is, in the absence of knowledge even of a finite degree of magnetic conductivity, a very far-fetched idea, yet it is useful in electromagnetic theory to contrast with the perfect electric conductor. A perfect magnetic conductor behaves towards displacement just as a perfect electric conductor does towards induction; that is, the displacement goes round it tangentially. It also behaves towards induction as a perfect electric conductor does towards displacement; that is, the induction meets it perpendicularly, as if it possessed exceedingly great inductivity, without magnetic conductivity. This magnetic conductor is also perfectly obstructive internally, and is a perfect reflector, though not quite in the same way as electric conductors. The tangential magnetic force and the normal electric force are zero.

As regards waves, there are two extreme ways in which a perfect conductor behaves—that is, extreme forms of the general behaviour. It may wholly conduct them, or it may wholly reflect them. In the latter case we may illustrate by imagining a thin plane electromagnetic sheet, consisting of crossed electric and magnetic forces in the ratio given by $\mathrm{E}=\mu v\mathrm{H}$, moving at the speed of light, to strike a perfect conductor flush—that is, all over at the same time, by reason of parallelism of the sheet and conducting surface. The incident sheet is at once turned into another plane sheet, which runs away from the conductor as fast as it came. If the conductivity be of the electric kind the reflected sheet differs from the incident in having its displacement reversed, but in no other respect. This is perfect reflection with reversal of **E**. During the act of reflection, whilst the incident and reflected sheets partly coincide, **E** is zero and **H** is doubled. Both are tangential; but there can be no tangential **E**, so the reflector destroys **E** and initiates the reflected sheet, in which **H** is the same as in the incident sheet, whilst **E** is reversed.

On the other hand, when the conductivity is of the magnetic kind, the reflected wave sheet differs from the incident only in having its induction reversed. The displacement persists, being doubled during the act of reflection, whilst the induction is then annulled.

The other extreme occurs when a plane electromagnetic sheet hangs on to a conductor perpendicularly. It then slips along the conductor at the speed of light, with perfect slip. This may occur with a plane reflector, but, of course, the most striking and useful and practical case is that of a straight cylinder—a wire, in fact, though it need not be round, but may have any form of section. The wave then runs along the wire at constant speed v, and without change of type, at least so long as the wire continues straight and of unchanged section. If the section vary regularly, so that the wire is a cone, then it is a spherical wave that is propagated along it without change of type. This case includes an infinitely fine wire, when we may have either spherical or plane waves. Other interesting cases may be made up by varying the angle of the cone, or using a double cone, or a cone and a plane, &c.

Now, in the first main case of perfect reflection (flush) the incident and reflected sheets are wholly separated from one another, except just at the reflecting surface, where there is a momentary coincidence. On the other hand, when a plane wave runs along a wire, or, say, more conveniently here, along a plane, we only see one wave. It is the case of reflection at grazing incidence, and may be considered the limiting case of permanent union of the incident and reflected waves. Between these two cases we have the general case of incidence and reflection at any angle. There are two plane waves (sheets, most conveniently for reasoning and description) one going to and the other coming from the plane reflector, where they join together, making equal angles with it. In the overlapping region, close to the plane, the displacement due to the union of the two waves is normal to the surface (that is, with an electric conductor) which is electrified, and the electrification runs along the surface at a speed depending upon the angle of incidence, being v at grazing incidence (of rays) and $v/\cos\theta$ at incidence angle θ, varying, therefore, between v and infinity. It may be, perhaps, rather a novel idea to some readers that electrification can run through space at any speed greater than that of light, but the matter is made simple enough by considering the rate of incidence upon the reflecting surface of different parts of the plane sheet. In the case of nearly flush incidence of a sheet, its different parts strike the surface nearly simultaneously, so that there is an immensely great speed of motion of the electrification along the surface. The electrification is the same in amount always, and is continuously existent, so we are somewhat justified in speaking of the electrification moving; but we may equally well regard it as a case of continuous generation of electrification at one end and of annihilation at the other end of the part of the conducting surface which is momentarily charged, the generation and annihilation being performed by the different parts of the incident sheet and the reflected sheet as they reach and leave the surface. Details of these simple cases, leading to a plainer understanding, will come later, when these general notions are got over. In the limiting case of normal incidence of rays, when the incident sheet strikes the surface flush, the electrification is non-existent. It goes out of existence just as its speed becomes infinite.

The above describes one extreme kind of reflection of a plane sheet at any angle, and is what occurs when **H** in the incident, and, therefore, also in the reflected wave, is tangential to the reflector, whilst **E** is in the plane of incidence. But when it is **H** in the incident wave that is in the plane of incidence, and **E** is tangential, we have quite another kind of composition in the overlapping part near the reflector. There is no **E** within it at all, and also no electrification; whilst the **H** within it is parallel to the reflector, and simply joins together the **H**'s in the parts of the waves which do not overlap, the **H** in one wave being directed towards the surface in the plane of incidence, and in the other away from the surface. In both waves, of course, **H** is in the plane of the wave. In other respects we have a similarity in propagation. It is now a surface current, instead of electrification, that runs along the surface at speed $v/\cos\theta$.

If the reflector be a magnetic conductor, we have two very similar main cases, in one of which magnetification (the analogue of electrification), and in the other a magnetic current runs, or appears to run, along the surface.

(To be continued.)

THE GERMAN ELMORE WORKS.

BY CLARENCE P. FELDMANN.

The newly-erected works of the Elmore's Metall Aktiengesellschaft are situated at Schladern, Rhenish Prussia, about 40 miles from Cologne, on the left bank of the Sieg, and not more than 300 yards from the railway station. The Sieg, which flows into the Rhine, winds its way in several large and nearly closed curves through the hills, and is able to furnish about 720 cubic feet of water per second. By negotiating one of these curves, and driving two 250ft. tunnels, it was possible to get a total fall of 18½ft., which, as the whole mass of water can be utilised, renders a total of 1,200 H.P. available.

The frontage of the factory (Figs. 1 and 2) measures 390ft., with a depth of 54ft., and at some parts 96ft. Most of the buildings have two floors. An embankment protects the whole building from the river, and, besides, it is situated so favourably that it cannot be injured by high-water or drifting ice. The main building is shown in plan in Fig. 1. The room A

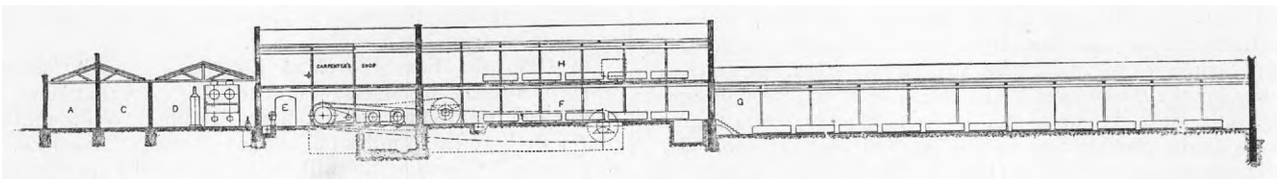

FIG. 2.—Sectional Elevation of the German Elmore Works near Cologne.

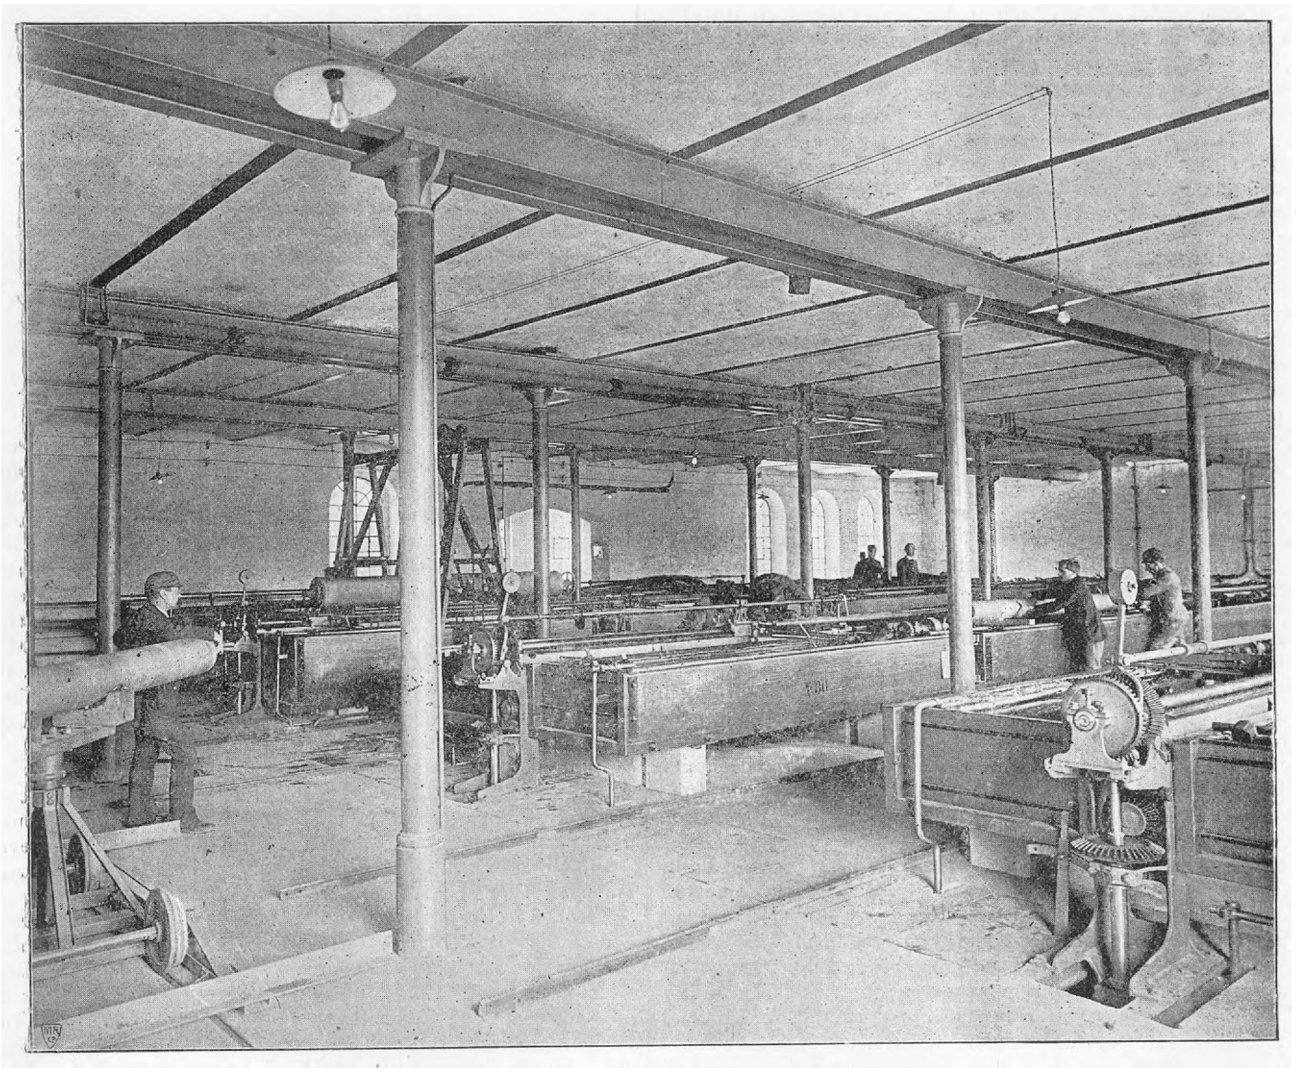

FIG. 3.—General View of Tank Room at the German Elmore Works near Cologne.

Hosted by Google

serves as a smithy, room B as a laboratory, room C as a store. The boiler-house, D, contains one tubular boiler, with a heating surface of 1,270 square feet, and one small boiler with vertical tubes, having a heating surface of 90 square feet. The engine-room is at E.

Of the total available water-power of 1,200 H.P., only 550 H.P. have been made use of so far. Two Knap turbines, by Messrs. Briegleb, Hansen, and Co., of Gotha, have been laid down, and the power is transmitted by rope gearing to a common shafting in such a way that one or the other, or both turbines may be coupled or disconnected by means of suitable couplings. Great care has been given to the bearings of the shafting, which are all provided with loosely-revolving lubricating rings. In spite of the rather high number of 160 revolutions per minute one of the wall bearings, which cannot be controlled during active service, made a record run of three months' continuous running, and was found to be quite intact when it was refilled with oil. This feature, small as it may seem to be, is an essential one, as with the Elmore process interruptions or disturbances might prove disastrous. From the common shafting the dynamos are driven by belts. They are four-pole Helios Company dynamos, running at 230 revolutions per minute, and having an output of 1,200 amperes at 50 volts. The main shafting also drives a small dynamo, which lights the building, and provides, by means of other auxiliary shafting, the necessary power for the tank-rooms. The engine-room has been designed for eight large dynamos and for one or more steam engines, which might possibly become necessary in very dry summers.

The tank rooms, F, G, H (Figs. 1, 2, and 3), are intended for 200 tanks corresponding to a total output of 35 tons a week. At present only 40 tanks are at work, and a second set of 40 tanks is just being put down. The tanks, similar to those of the Leeds works, allow of the production of tubes of 10ft. 8in. in length and 22in. diameter. All 40 tanks are connected in series. A room near the turbine house contains very large tanks, the special tanks, in which tubes of 15ft. length and 5in. diameter can be made. This room also contains the cyaniding tank in which all the iron cylinders, hydraulic rams, &c., get the first thin layer of copper before they are passed into the tanks containing the sulphate of copper solution. Small electric motors drive rotating pumps, which produce the circulation of the liquor in the tanks; other electric motors are directly coupled to circular tube saws and polishing discs. A powerful testing machine, fitted up in a special room on the first floor, is in continuous use. Not a single tube is sent away, the qualities of which with regard to tensile strength, elongation, and contraction, have not been carefully tested and registered. These figures, together with a most complete system of daily reports, allow a very complete control of the whole output, and the origin of every tube, and all circumstances connected therewith, can be traced back at any time.

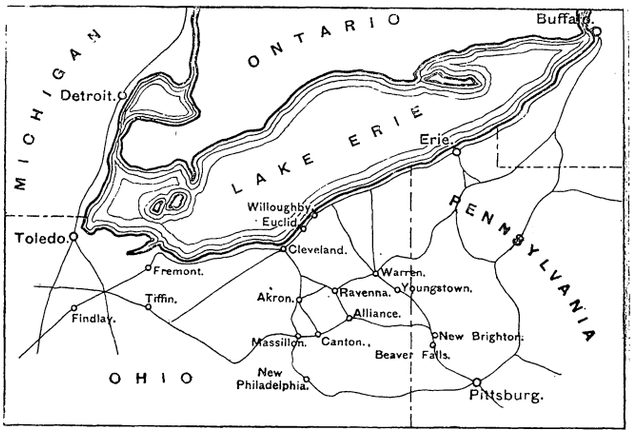
The greater proportion of the work done at Schladern is devoted to the production of tubes and the thickening up of calico rollers. Just lately another branch of the process has become of great importance, namely, the coating of seamless wrought-iron tubes. These tubes are first turned true on the lathe, and then covered with a firmly adhering copper deposit, varying in thickness from $\frac{1}{32}$in. to $\frac{1}{2}$in. The compound rollers obtained in this way are mostly employed in paper machines and in textile machines. They possess higher tensile strength than pure copper rollers without losing the advantages of the latter. It was also stated that large orders have come in lately for coating iron tubes for mining purposes inside and outside with a thin copper deposit, in order to protect them from oxidation. The adherence of the deposit to the rough iron surface is secured by a special process.

The situation of the works, which have been planned built, and are managed by Mr. Ernest Preschlin, in the midst of the most busy part of industrial Germany and close to the West Prussian Copper Mines, not only secures them skilled workmen and cheap raw material, but the selling facilities for their products are increased to a great extent, by the close vicinity of all the large German calico printers' establishments and paper mills. However, the splendid water-power is the main advantage which these works possess compared with their associated companies in other countries.

ELECTRIC RAILWAYS AND RAILROADS IN AMERICA.

Across the Atlantic a tramway invariably becomes a "railway," and a railway usually a "railroad." Before long nearly every "railway" in the United States appears likely to blossom out into a "trolley line," and American engineers, not content with the supremacy of the electric car in this direction, have several schemes now under weigh, which will bring electricity into more or less direct competition with steam "roads." A "Light Railway Bill" was passed by the Imperial Parliament a Session or two back, and as money has ever since been annually voted towards the construction of such lines, it may be presumed that the Act is not remaining a dead letter. It is to be regretted that the suitability of electricity for this purpose was not thoroughly threshed out by our obliging American friends in time to enable those directing the construction of the Irish Light Railways to profit by transatlantic experience, and to back up their statements by statistics of lines in actual successful operation. However, if the projects, said to be seriously contemplated in Ohio and Pennsylvania, are pushed forward with the rapidity customary in America valuable working data may yet be available in sufficient time.

In Ohio the East Cleveland Electric Railroad Company, which is already in possession of the streets of that town, has announced its intention of extending its line to Willoughby, a pretty little town 18 miles off, on the shore of Lake Erie. It is expected that the line will be largely used to carry grapes



and farm produce. A little further south it is proposed to connect Akron with Canton, 23 miles away, Canton with Alliance, 18 miles distant, and Alliance with Niles, by a road 25 miles long. A line is also contemplated between Warren and Youngstown, and another from Akron to Ravenna, 15 miles off. If the annexed sketch map be consulted it will be seen that in every case the proposed trolley lines will connect places already connected by steam "railroads." For some little time competition of this kind has already been successfully maintained in the case of the Canton-Massillon line, nine miles in length, the New Brighton—Beaver Falls line, and the New Philadelphia—Canal Dover line. The greater frequency of the cars and the lower fares are given as reasons for this state of things.

A project more ambitious than any of the preceding is one which is to be fathered by the Tiffin and Fostoria Electric Railway Company. It is proposed, first of all, to connect Tiffin with Fostoria, 13 miles away. This line will, however, only be one link in a system 100 miles in extent, connecting, amongst other places, Fremont, Fostoria, and Findlay.

Electric railways have up to the present a peculiar status in Ohio. They carry goods, passengers, mails, and are common carriers for an express company. In a word, they differ from other railways only in motive power used. Yet they are not amenable to the railway laws of the state. For this reason no official statistics are obtainable. No data are being collected for future use, although all such lines, being built along public highways and sometimes occupying part of the

Hosted by Google

roadway, enjoy exceptional privileges, and will in time call for special regulation.

In Pennsylvania a charter has been granted to a company which proposes to lay down a network of electric lines 80 miles in extent, and connecting 39 towns and townships. The Reading Railroad Company is said to be alarmed at the prospect.

In connection with electric "railways," the last annual report of the Board of Railroad Commissioners for the State of Massachusetts may be read with interest. The Report is, as usual, redolent of all manner of statistics, those relating to street railways being particularly full. We do not know whether any serious attempt is made to check the accuracy of these American returns, but if not, we are afraid little good can come of them, unless, perchance, "the coefficient of involuntary mendacity" is abnormally low in New England, as, indeed, on all principles of heredity it should be.

For the year ended September 30, 1892, the total length of street railway track in Massachusetts—which, we may observe, is somewhat larger than Wales—was 814 miles, being an increase of about 21 per cent. on the mileage for 1891. Of this total 492 miles, or 65 per cent, are operated in whole or in part by electricity. The increase in electric mileage over that of 1891 is no less than 70 per cent. One company, the Milford and Hopedale, runs accumulator cars; all the others are trolley lines.

The report deals with sixty street railway companies, having an aggregate capital of not far short of four and three-quarter millions sterling. The average total cost per mile of the 814 miles of street railway existing in Massachusetts works out at £9,471. The gross income of the sixty companies which sent in returns amounted for the year ended Sept. 30, 1892, to nearly two millions sterling. The net income was £471,262, an increase of 32 per cent. upon 1891. About £316,540 was paid away in dividends, an average of 6·72 per cent. on the total amount of capital stock, as against 5·63 per cent. for the previous year. One company paid a 10 per cent. dividend, one 9 per cent. three 8 per cent., and 39 companies declared no dividend at all.

The total number of miles run was 29,617,975, an increase of 7 per cent. The total number of passengers carried during the year was 193,760,783, an increase of 10 per cent. over the preceding year. The average sum received for the conveyance of a passenger was a trifle over 2½d., and the average cost of carrying a passenger was nearly 2d., the average net profit to the companies on a passenger was 0·61d., as against 0·5d. in the previous year. On the sixty roads included in the report there were 610 accidents, of which 26 were fatal, 300 of the total being on the West End Company's system in Boston. Some 66 per cent. of the accidents were on electrical lines, against 40 per cent., during the preceding twelvemonth, the number of motor cars having doubled.

The report includes references to "fenders," or cowcatchers, and the noise made by the electric cars; the West End Company, of Boston, reporting that it has tested 43 "fenders," one of which, the Cleveland, has up to the present proved entirely successful.

THE AMERICAN PROPOSALS WITH REGARD TO ELECTRICAL UNITS.

Our Paris correspondent sends us the following *résumé* of the discussion on the recent proposals of the American Institute of Electrical Engineers with regard to electrical units, which took place last Wednesday week at the Société Internationale des Électriciens. A summary of these American proposals appeared in our issue of February 3rd :—

M. BLONDEL was of opinion that the definition of "impressed electromotive force" was a bad one, and tended to confusion. He demanded its withdrawal. He wished to keep the expression "difference of potential," and considered "voltage" slang. In his opinion there was no need to replace the word "permeability" by "inductivity," which did not appeal to the mind so much. The Committee of the American Institute of Electrical Engineers had defined "reluctivity" inaccurately, and the need for the term was by no means self-evident. He would suggest that the unit of illumination, the *lux*, should be equal to that of one bougie at one metre. He did not agree with the adoption of the Hefner-Alterneck amyl-acetate standard, which was difficult to use and of insufficient accuracy, whilst the carcel, or, better still, the Violle standard, were much more accurate. The speaker then exhibited a standard arc lamp based on the fact that the intrinsic brilliancy of the arc was constant. He (M. Blondel) had experimented, together with M. le Chatelier, upon carbons of various qualities, and had not observed any variation in their intrinsic brilliancy.

M. GUILLAUME suggested that the termination "ity" should be reserved for properties of matter—for example, "resistibility"; whilst the termination "ance" should denote a fraction—for instance, Resist*ance* = Resistibil*ity* × S/l. The term "inductance" was unnecessary. "Inductivity" was useless; moreover, there was an error of sign in its definition. The word "permeability" was handier. He would support the names of "gauss" and "weber," but not those of "gilbert" or "oersted." In any case, the size of the practical units should be such that the system was coherent.

M. HOSPITALIER voted for the radical abolition of the expression "bougie-metre"; the unit of illumination was the bougie at one metre. M. Hospitalier then read a letter which he had received from M. Potier with which he entirely agreed. M. Potier held that the units should not be called absolute but merely C.G.S. The "weber" was useless, since the C.G.S. unit of both total magnetic flux and of magnetomotive force sufficed. "Inductivity" had no *raison d'être* since we had "permeability." The expression *flux* was simpler and less ambiguous than "total induction." There was no need to give a special name to the ampere-hour or kilowatt-hour.

The discussion was then adjourned to the next meeting.

MEETINGS OF SCIENTIFIC SOCIETIES, &c.

(TO-DAY) FRIDAY, March 10th.

PHYSICAL SOCIETY.

5 p.m. Papers to be read: (1) "The Application of Lagrange's Equations of Motion with especial reference to a Perforated Solid in a Liquid," by Dr. C. V. Barton; (2) "On the Magnetic Field of a Circular Current," by Prof. G. M. Minchin, M.A.; (3) "On the Differential Equation of Electrical Flow," by T. H. Blakesley, M.A.

INSTITUTION OF CIVIL ENGINEERS.

7:30 p.m. Students' Meeting. Paper to be read: "Methods adopted in constructing the Glasgow Central Railway Works—Bridgeton and Trongate Contracts," by Charles D. Barker, Stud.Inst.C.E.

ROYAL INSTITUTION.

9 p.m. Evening discourse: "Early Myth and Late Romance," by Sir Herbert Maxwell, M.P.

SATURDAY, March 11th.

ROYAL INSTITUTION.

3 p.m. Afternoon Lecture: "Sound and Vibrations," by Lord Rayleigh, F.R.S.

MONDAY, March 13th.

SOCIETY OF ARTS.

5 p.m. Cantor Lecture (2): "Alloys," by Prof. W. Chandler Roberts-Austen, F.R.S.

TUESDAY, March 14th.

INSTITUTION OF CIVIL ENGINEERS.

8 p.m. Ordinary Meeting. Paper to be further discussed: "On Plant for Harbour and Sea Works," by Walter Pitt, M.Inst C.E.

WEDNESDAY, March 15th.

INSTITUTION OF CIVIL ENGINEERS.

2 p.m. Students' Visit to the East London Water-works, Lea Bridge.

ROYAL METEOROLOGICAL SOCIETY.

7 p.m. Ordinary Meeting at the Institution of Civil Engineers. Lecture: "Some Meteorological Problems," by Mr. Shelford Bidwell, F.R.S. (Illustrated by experiments).

SOCIETY OF ARTS.

8 p.m. Ordinary Meeting. Paper to be read: "Technical Education: Its Progress and Prospects," by Sir Philip Magnus.

THURSDAY, March 16th.

CHEMICAL SOCIETY.

8 p.m. Ordinary Meeting. Papers to be read.

FRIDAY, March 17th.

INSTITUTION OF ELECTRICAL ENGINEERS.

8 p.m. Students' Meeting. Paper to be read: "Turbines," by C. V. Drysdale.

ROYAL INSTITUTION.

9 p.m. Evening Discourse. "Ancient Egyptian Pigments,' by Dr. W. J. Russell, F.R.S.

SATURDAY, March 18th.

ROYAL INSTITUTION.

3 p.m. Afternoon Lecture: "Sound and Vibrations," by Lord Rayleigh, F.R.S.

*** **Particulars of meetings to be held or Papers to be read before Scientific Societies during the ensuing week should reach us not later than Thursday, 6 p.m.**

Hosted by Google

The Electrician.

Published every Friday, Price Fourpence; Post Free, Fourpence Halfpenny.
Editorial, Publishing, and Printing Offices :

SALISBURY COURT, FLEET ST., LONDON, E.C.

Telephone No. 2714. *Telegrams :* "ELECTRICIAN NEWSPAPER, LONDON."

All Letters relating to Subscriptions, Advertisements, and other business matters should be addressed to the Publisher, "THE ELECTRICIAN," *Salisbury-court, Fleet-street, London, E.C. Cheques and Money Orders should be made payable to* "THE ELECTRICIAN" *Printing and Publishing Company, Limited, and be crossed "Coutts and Co."*

All Editorial letters to be addressed to the Editor.

All letters intended for insertion in "THE ELECTRICIAN," *or containing questions, must be accompanied by the name and address of the writer, not necessarily for publication, but as evidence of good faith. No notice whatever will be taken of anonymous communications.*

"THE ELECTRICIAN" *is published every Friday morning, in time for the morning mails.* "THE ELECTRICIAN" *is on sale at the railway bookstalls throughout the Kingdom on Friday morning, and can be obtained of all Booksellers and Newsvendors; or direct from the Publishing Offices.*

New Volumes of "THE ELECTRICIAN" *commence in May and November. Old Back Numbers and Volumes of* "THE ELECTRICIAN" *are frequently wanted, and offers will be made by the Publisher therefor.*

Subscription Rates.—The rates for Subscriptions to "THE ELECTRICIAN" are as follows :—

	3 months.	6 months.	12 months.
	s. d.	s. d.	s. d.
For the United Kingdom	5 0	10 0	19 6
For Foreign Parts and Colonies :—			
Within Postal Union	6 6	12 6	24 0
For Aden, Borneo, Ceylon, China, India, Japan, Java, Labuan, Mozambique, New Caledonia, Persia, Phillippine Islands, Siam, Transvaal, and Zanzibar	7 6	14 6	28 0

TO ADVERTISERS.

"THE ELECTRICIAN" *offers exceptional advantages to Advertisers.* **It has by far the largest circulation of any English Electrical paper, and circulates all over the World.**

Advertisement Rates, &c., forwarded on application as above.

TRADE ADVERTISEMENTS *intended for the current issue must reach the Offices not later than First Post on Thursday. Renewals of expiring advertisement orders and alterations to standing advertisements must be in Publisher's hands by Wednesday at latest. No alteration can be made in Wrapper Advertisements after Wednesday morning.*

SMALL ADVERTISEMENTS *accepted up to 4 p.m. Thursday.*

ELECTRICAL BOOKS AND PUBLICATIONS.

All Books, Newspapers, and other publications, dealing with Electrical and kindred subjects, can be ordered direct of "THE ELECTRICIAN" *Printing and Publishing Company, Limited, who are proprietors of the well-known* "ELECTRICIAN" SERIES *of Standard Electrical Works, and are Agents for all the leading publishing houses at home and abroad.*

"THE ELECTRICIAN" SERIES *at present consists of—*

THE ALTERNATE CURRENT TRANSFORMER IN THEORY AND PRACTICE. By Dr. J. A. FLEMING.
VOL. I.—THE INDUCTION OF ELECTRIC CURRENTS. Price 7s. 6d., post free.
VOL. II.—THE UTILISATION OF INDUCED CURRENTS. Price 12s. 6d., post free.

MAGNETIC INDUCTION IN IRON AND OTHER METALS. By Prof. J. A. EWING, M.A. Price 10s. 6d., post-free.
The same in German, price 8s. 6d., post free.

THE ART OF ELECTROLYTIC SEPARATION OF METALS (Theoretical and Practical). By Dr. GEORGE GORE. Price 10s. 6d., post free.

ELECTRO-CHEMISTRY. By Dr. GEORGE GORE. Price 2s., post free.

PRACTICAL NOTES FOR ELECTRICAL STUDENTS. By A. E. KENNELLY and H. D. WILKINSON. Price 6s. 6d., post free.

THE STEAM ENGINE INDICATOR AND INDICATOR DIAGRAMS. Edited by W. W. BEAUMONT. Price 3s. 6d., post free.

A DIGEST OF THE LAW OF ELECTRIC LIGHTING. By A. C. CURTIS-HAYWARD, B.A. Price 2s. 6d., post free.

THE MANUFACTURE OF ELECTRIC LIGHT CARBONS. A Practical Guide to the Establishment of a Carbon Manufactory. Price 1s. 6d., post free.

ELECTROMAGNETIC THEORY. By OLIVER HEAVISIDE. [*Nearly ready.*

A POCKET BOOK OF ELECTRICAL ENGINEERING FORMULÆ. By W. GEIPEL and H. M. KILGOUR. [*Nearly ready.*

DRUM ARMATURE WINDING, AND COMMUTATORS: In Theory and Practice. By F. M. WEYMOUTH. [*Nearly ready.*

SUBMARINE CABLE LAYING AND REPAIRING. By H. D. WILKINSON. [*In preparation.*

ELECTRICITY AS A MOTIVE POWER. By A. T. SNELL. [*In preparation.*

Now Ready, in Two Volumes. Prospectuses Free.

Full Digest on Application.

MODERN DYNAMO EFFICIENCY.

While electrical engineers may justly claim to have shown the world how efficiencies of machines may be measured to a hitherto undreamed of accuracy, and while they may indeed be said to have firmly established the true meaning of the word efficiency, as the ratio of work expended to work returned, and while they have crowned their teaching by the practical achievement of one of the most efficient machines that has ever been constructed, it is a question whether, intoxicated with the glories of 96 and 97 per cents., they are not in danger of being carried away with the enthusiasm for an ideal; an ideal which is not an end in itself, but only a factor of success. "Efficiency be hanged!" said a speaker at a recent meeting in Great George-street. It is hardly necessary to say that it was not a meeting of the Institution of Electrical Engineers. The denunciation raised only a laugh, but among electrical engineers would it not have been received with scorn? Not only is high efficiency merely a factor, but it is only one of several factors of success; for besides efficiency, sound mechanical construction, first cost, and in

Hosted by Google

some cases weight, are of at least equal importance. Ingenious, and indeed startling, calculations may be made of the capitalised value of the saving effected by a high efficiency, and by proper handling of the figures it may be shown that a machine of this kind will pay for itself after a very few years. But, unfortunately, the cost of repairs cannot be estimated with any such facility. The racking of alternators and cutting of dynamo commutators, burned out armatures, worn brasses, and a score of items short of actual breakdowns, must all be set against this saving. More than this, almost every repair entails anxiety and additional supervision, besides possible annoyance to consumers, while a steady loss by a slight reduction of efficiency is to be detected only in the coal bill, and that only by calculation. We do not for a moment advocate any retrogression in a matter on which electrical engineers take such legitimate pride, but we do not hesitate to say that £20 a year spent in additional coal *and nothing else*, is better than £5 a year spent on additional repairs, and that the expenses consequent on a robust appetite are preferable to a succession of doctor's bills.

Among a class of young electrical engineers there appears to be a positive enthusiasm for high efficiencies in dynamos, and were reliable tests more commonly published, record-breaking would be watched with intense interest. But a central station with a dozen dynamos costing half-a-crown a piece per annum for repair, would pass unnoticed by these devotees of the high ninties. Not only does a slight increase of the coal bill fail to force itself unpleasantly on the notice of the engineers, but a diminution of repairs is necessarily accompanied by greater certainty of continuity in supply. The old Edison dynamos with all their faults, faults which the eager student can count off on his fingers with ease, ran for months and years without costing a penny. As a rule, they were run at what might be called about half-load, as far as their dimensions and weight were concerned, and many an enterprising owner has regretted changing them for the latest improvements, or has had very unfavourable comparisons forced upon him when his plant has been increased by the addition of modern machines. A most striking case of shocking efficiency combined with admirable running—perfection of running, in fact—is to be found in the De Meritens machines at St. Catherine's Point Lighthouse. Alternators with permanent magnets of the horseshoe shape seem archaic compared with our carefully selected forgings, our ampere-turns, our B, our cleverly-shaped pole-pieces, and our carefully-designed magnetic circuits; but we should like to hear an interchange of experience between their drivers and the staff of some modern supply station, on management and repairs. The builder of a machine with a marvellous efficiency is applauded for the cleverness of the design, and the figure remains as a permanent stamp of merit. The machine breaks down, and it is called an accident. Perhaps the mechanical construction might have been improved, and probably will be improved next time. The breakdown, it is said, was probably an accident, but the wonderful efficiency was no mere chance, but a highly scientific achievement. The secrets of the science of the high nineties may be taught, and are, we believe, commonly taught in lecture rooms. The true art of building a machine cannot so be taught, though praiseworthy attempts are sometimes made to do so. The elements may be discussed and the principles may be inculcated at colleges, but the art can only be learned in the shops. Electrical efficiency is easy enough to attain; so-called commercial efficiency is harder; but financial efficiency is as yet unrecognized, but should be the ambition of the dynamo builder.

AMBERLEY ROAD STATION.

The latest addition to the electric supply stations of London is that of the Metropolitan Company at Amberley Road, Paddington. The position of this station is marked on the coloured map which was issued as a supplement to *The Electrician* of January 13, 1893, and is at the extreme north-west corner of that part of the Metropolitan Company's district in which mains have been laid. The station is situated at St. Peter's Wharf, a site which has the advantage of both road and water access. The buildings consist of a boiler-house with coal store fronting the canal; engine-room and dynamo-room; and suitable offices and store rooms fronting the road, the upper floors over the offices being planned for the accommodation of the staff. After their experience of the practices of London building contractors, the Company decided to design and build their own station, the services of Mr. Mark Judge being retained chiefly for the purpose of smoothing off the difficulties which always arise in connection with the Metropolitan Building Act. The erection work proceeded without interruption through the period of the recent strikes in the building trade.

The engine-room is of ample proportions and is excellently lighted; it resembles a large country station, and is very different from most of the cramped and half-buried London stations. It contains five large horizontal engines by Hornsby, each driving a Kapp 100 kilowatt alternator by ropes. The driving centres are about 27ft.; and the speeds are 100 and 500 revolutions per minute. The contractors for the plant were Messrs. Johnson and Phillips, but owing to lack of time the alternators were made at the Oerlikon Works, Zürich. These machines reveal their continental origin in one or two minor points of construction, but seem to be excellently adapted for their work. They give 100 amperes at 1,000 volts, but will probably carry a heavier current. The design of the machines allow free access to all the parts, but without undue floor space or straggling proportions. In view of the necessity for avoiding all noise and vibration in a London station, Mr. Frank Bailey has made several experiments to obviate the hum which was set up by the rather open armature. Filling up the spokes of the wheel-like armature with wood did not produce any appreciable effect, while it rather spoilt the look of the machine, but wood filling between the armature coils effectually silenced the noise. The engines are provided with balanced governors controlling the eccentric by means of a link, and on the occasion of the visit of the Paddington Vestry on Friday last, one set was under steam on an artificial load, while two others were coupled together electrically, one alternator running as a motor and driving its engine, the cylinder and valve chest covers being removed. The steam piping is of interest, being constructed of electrically welded pipe by Messrs. Lloyd and Lloyd. A feed water-heater is provided, but no economiser. With such ample supply of water literally at their very doors, the Company is most unfortunately debarred from using it for condensing purposes, or rather, from returning it hot, to the canal. The contractors would no doubt have built the alternators at their Charlton works had time permitted, but we regret to find that not only have these come from Switzerland, but the measuring instruments on the switchboard were "made in Germany," and very much so. It is easy to understand that cheap German instruments are put on the English market by importers, but they are hardly to be expected in a first-class station equipped by such a firm of contractors as the present ones. Some of these instruments appeared to be trying to read volts, and others amperes, possibly they were German volts, certainly not Reichsanstalt volts, for these are almost the same as B.A. volts, "legal" volts, Board of Trade volts, or British Imperial volts. Like a country yokel struggling over a letter with his head on one side, the instruments were tilted

Hosted by Google

at all sorts of angles to accommodate them to the climate or to the Kapp variety of current.

We understand that it is proposed to make no attempt to run the alternators in parallel, the switchboard is arranged for grouping the various circuits on any machines. The switchboard, placed in a gallery, is constructed of marble, and the mains, of Silvertown make, are brought into the engine-room through subways. Mr. Frank Bailey's system of ring mains, providing each customer with a duplicate supply, is carried out in the district served by this station.

One central station is very much like another, and on the occasion of the visit of the Paddington Vestry, the greatest novelty was a counter on which Messrs. Crompton and Co. exhibited electrical cooking appliances. Outside the buildings, however, we found something of considerably greater interest, but attracting no attention whatever from the visitors. This was the artificial load on which one of the alternators was running, and on which efficiency tests had been carried out. Nothing was visible but a gallows of three scaffold poles, one or two rope stays and a pair of cables disappearing into the water of the canal about 12ft. apart. The presence of half a-dozen dead or dying sticklebacks appeared to be accidental, and between the cables a board moored by cords carried a glowing 16-candle lamp. Some days ago before this little light-vessel was put down a barge load of iron pipes arrived at the wharf, and a bargee on landing was heard to indulge somewhat more freely than usual in the language of his tribe. Standing on the dry campshed, and holding a crowbar in the water, we received a slight shock, for beneath the surface two iron plates about 3ft. by 3ft. were suspended from the cables, and though not a bubble was to be seen, some 75 amperes at 1000 volts were expending themselves in the muddy fluid. The little lightship, a caution to bargees, owed its supply of energy to precisely those principles on which it has been proposed to signal to lightships from the shore. Two plates 18in. square were hung from the board, and when set between and parallel to the large plates, the lamp glowed; when swung round at right angles it was extinguished. We had no opportunity of studying the effect of the current on the little fish. On coming within two or three yards of the midway point between the plates, they appeared to be fascinated by the gratuitous electropathic treatment, and when well within the lines of flow turned over, and with a kick or two, became rigid.

SPARKING AT COMMUTATORS.

BY F. M. WEYMOUTH.

(*Continued from page 513.*)

Fig. 17 may now engage our attention. This represents in detail the brush in position C (Fig. 15), where it is shifted too far forward of the *N P* plane, which latter is indicated in both diagrams. It will first be noted that the coil *b* here carries the 500 s.-c. current instead of *f*, as in the last case, and it is a resultant 50 amperes of the *b* s.-c. that enters by lug *h*. There is thus a normal 450 assimilated s.-c. current entering through *i*, and a normal 500 s.-c. current flowing out through lug *g*. Now to consider the *c* main current, we find this attempting to enter through *g*. Being blocked, however, by the outflowing *b* s.-c. 500, it becomes assimilated with the latter in the coils *b* and *f* instead, in the same manner as the *d* current in the previous case. We then find the 450 entering by lug *i* to be composed of 200 assimilated *d* plus 250 s.-c. currents. To this latter is now added the 200 *d* main current, making a total *resultant* current of 650 amperes entering by this lug. Arriving at *o*, however, 400 amperes split off to ascend the brush, thus leaving only 250 to continue to *n*. At this latter point it is joined by the 50 *b* s.-c. current, making the 300 outflowing through *g*. Thus again is the cycle completed.

Now here there are various points to be noted. First, it is *not the main d and c* currents that are broken, for these have both a free entry into the brush through its *heel* instead of the point; and the heel continually *makes* contact with the segments, one after the other, instead of breaking contact, as compared with the case of the brush at A. It is thus the coils *behind* the brush that are reversed, and not those just leaving the point. The effect will then be that the momentary check due to the self-induction of the coil *f* will cause the reduction of the 650 in lug *i* to 50, as it arrives at position *h*, to be *gradual* instead of sudden. We shall return to this, however, in connection with the line *CnP*. The point to which we would now draw attention is thus, secondly, that it is only

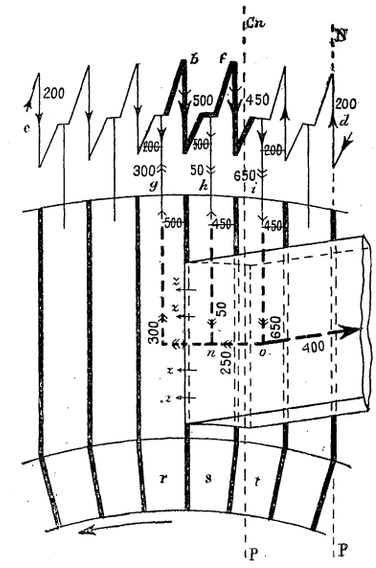

FIG. 17.—Positive Brush too far forward. Light Back Sparking. (Position C in Fig. 15.)

a *short circuit current* of 300 amperes that is broken at the recession; and further, that this is running in the *opposite direction to the main current* flowing up through the brush. We have here, hence, what has been termed "back-sparking," as indicated by the arrows *z z* in Figs. 15 and 17. Being due, moreover, to the self-induction of the coils *b* and *f* only, the

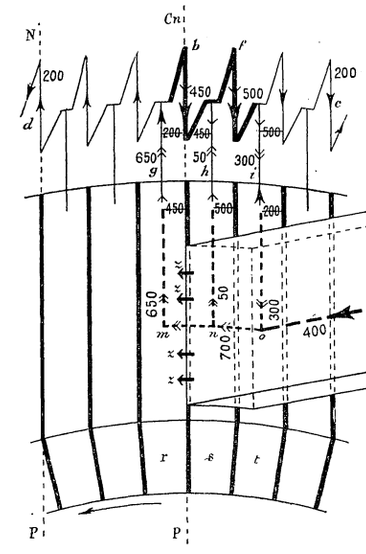

FIG. 18.—Negative Brush too far back. Heavy Forward Sparking. (Position B in Fig. 16.)

sparking is slight; while the current broken being but 300 instead of 400, or 650 as in the last case, the arcing is not so heavy. The brush, however, being positive, will incur most of the burning.

We now come to Fig. 18. This represents the lower brush in position B. As it would have been confusing to invert the diagram to make it accord with the actual position of the brush on the commutator, we do not do so, and merely indicate the

Hosted by Google

main current *entering* by the brush instead of leaving. It will be seen here that the brush is too far back, like brush A; while of the two short-circuited coils, *f* carries the 500 amperes, being nearer the plane *y y*. The first point that may be noted is that the difference between the *b* and *f* s.-c. currents, that is, the resultant 50, instead of flowing inwards in the lug *h*, is here flowing outwards. A normal 450 s.-c. current outflows through lug *g*; and a normal 500 s.-c. current enters by *i*. But now the main current from the outer circuit arrives by the brush at *o*. Its natural course being to split and send 200 to the *c* coils and the other 200 to the *d* coils, the first-named 200 tries to obtain exit by the lug *i*. Here, however, it is baulked by the normal inflowing 500 *f* s.-c. current. This latter hence becomes reduced to a resultant 300 in *i o*, as indicated. Consequently, the first 200 becomes assimilated with the *f* current in *o n*; and being joined there by the other 200 entering by the brush, a total of 700 proceeds to *n*. Here the 50 pass up *n h*. The remaining 650 runs on to *g*, at the outer end of which 200 diverges into the *d* series of coils, while the 450 runs through *b*. This is joined by the resultant 50 up *h*, making 500 amperes in the coil *f*. At the outer end of *i* 200 separates into coils *c*, leaving the 300 to continue down *i*, as we found at the commencement.

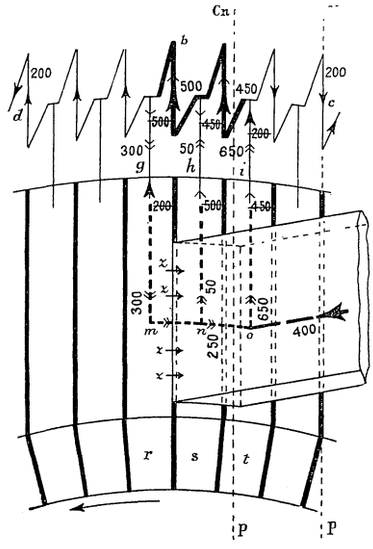

FIG. 19.—Negative Brush too far forward. Light Back Sparking. (Position D in Fig. 15.)

What we may here note is that the current broken at the recession is the *whole outer main current*, plus 250 amperes of the short circuit current. There is the whole self-induction of the outer circuit, together with the added effects of the short circuits, thus brought into play. As the outer circuit may include the field magnet coils, the sparking may here be very heavy; and with the large current, considerable burning will take place, principally, as it will be seen, at the expense of the brush.

The diagram (Fig. 19) may now engage our attention. The coil *b* here carries the 500 s.-c. current, and a resultant s.-c. 50 flows out through the lug *h*, as in the previous case. A normal 500 s.-c. current inflows through *g*, and a normal s.-c. 450 outflows through lug *i*. The 400 from the outer circuit now arrives at *o*. Of this, 200 would pass to the *d* series by lug *g*, but being met by the inflowing 500 *b* s.-c. current, reduces that to 300 instead. It becomes assimilated with the s.-c. current, and so forms part of the 450 s.-c. current outflowing through lug *i*. The remaining 200 of the outer current augments this 450, thus making a total of 650 finding exit by lug *i*. At the outer end of this lug, 200 splits off to enter the *c* series of coils, while the 450 continues through *f*. This latter amount is joined by the 50 s.-c. current from *h*, making 500 amperes in coil *b*. Of this, 200 diverges into the *d* series, leaving the 300 to continue down lug *g*. Arriving at *n*, the 50 pass up *n h*, leaving only 250 to proceed to *o*. So the cycle of operations is once more completed.

It will now be noted that we have back-sparking here, as in the case of the brush in position C; for it is the contrary direction to the main current. Moreover, as in the latter case, there are only 300 amperes broken, and that but short-circuit current. Thus, the sparking will be only that due to the self-induction of the short-circuited coils *b* and *f*. It will hence only be slight, and with the small current the arcing will not be great, though the segment will suffer the most. As with the brush C, the main current passes through the heel of the brush, and not the point, and so escapes being broken.

(To be concluded.)

CONCENTRIC CABLE PHENOMENA IN ALTERNATE CURRENT WORKING.

BY L. NEUSTADT.

It was noticed in a large network of concentric cables traversed by an alternating high-pressure current, that the insulation was often destroyed when a section of cable was switched in or cut out during the working, or if a cable-fuse went. In most cases the damage was done to the insulation between the outer conductor of the cable and the sheath, which is, of course, generally somewhat thinner than that between the two conductors. This phenomenon, which was frequently observed in

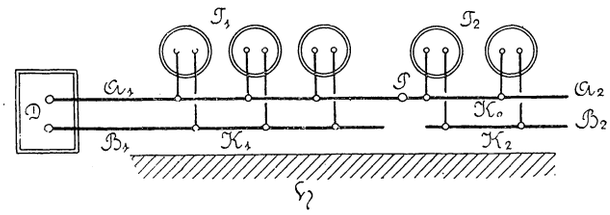

FIG. 1.

a large network embracing about 85 kilometers, occurred also in such cables as not only left nothing to be desired as far as insulation was concerned, but in which the insulation had been experimentally tested before laying with a pressure many times the normal working voltage, without sustaining injury of any kind whatever. The puncture only occurred when the inner conductor was coupled first (in the case of a joint being effected), or conversely if the outer conductor was first disconnected, and when the section in question contained transformers, which had either open or very lightly-loaded secondary circuits. The cause of this phenomenon, which may have very serious effect on working, is the subject of the following remarks.

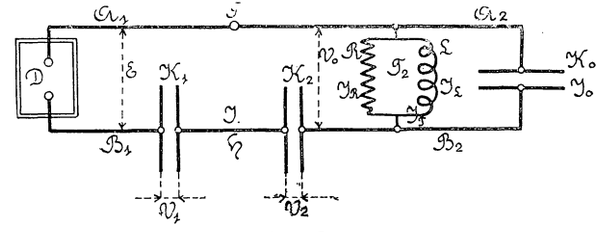

FIG. 2.

In Fig. 1 let D be the generator, delivering an alternating current into the cable, of which A is the inner and B the outer conductor, and let T represent transformers and K the condenser formed by the outer conductor B and the sheath H of the cable, which is of course earthed. Let K_0 be the condenser which is formed by the inner and outer conductors of the cable. The point of junction of the two parts of the inner conductor A is at P. Indices (1) indicate the parts of the system coupled to the dynamo, and indices (2) apply to the parts connected only by the inner conductor at P to the system. In this investigation I shall suppose that the insulation of the cable network is perfect, and that there are no concentric cables in the secondary network.

Hosted by Google

One circuit is formed by the dynamo T, the conductor $A_1 B_1$, and the primary of the transformer T_1; another circuit, the one with which we are concerned, and which is diagramatically shown in Fig. 2, is formed by the dynamo T, the conductors $A_1 A_2$ and B_2, the transformers (with little or no load on) T_2, the condensers $K_0 K_1 K_2$, and the outer sheath H (earth). Call the voltage at the terminals of the dynamo E, and assume that E may be expressed by the simple formula,

$$E = \sqrt{\frac{r}{2} \int_0^{\frac{2}{p}} (E_0 \sin p\pi t)^2 \, dt}.$$

and neglect any drop of volts which takes place in the cable itself. Let I be the current in the circuit we are examining, L the coefficient of self-induction of the transformer system T_2; let R be a resistance which represents the equivalent of the losses by hysteresis eddy currents and load in the transformers, according to the formula

$$W = V_0^2/R.$$

and V_0 represent the pressure at the transformers.* The phenomena are easily explicable if we assume that K_1 is very great compared with K_2 and K_0 is very small compared with K_2, and that we are dealing with an ideally good unloaded transformer, so that

$$R = \alpha \qquad K_1 = \alpha \qquad K_0 = 0.$$

This assumption leads to the case shown in Fig. 3, under which circumstances it is well known that in certain cases the voltage at L and K_2 may be many times higher than that at the terminals of the machine.

Returning to Fig. 2, suppose for the sake of further investigation that V_0 represents the pressure at the group of transformers T_2—that is to say, the voltage between the conductors of the cable; and that V_2 represents the voltage at the condenser K_2—that is to say, the pressure between the outer conductor and the sheath or earth. For I_1, V_0, and V_2 values can

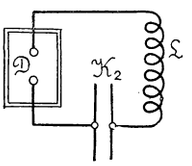

Fig. 3.

be found in terms of E under the foregoing assumptions, which I write down as the result of somewhat tedious though easy calculations, without trying the patience of readers with the full working of formulæ which rest on assumption which are not entirely justifiable.

$$I = E \times \frac{p \,.\, \pi \,.\, K_1 K_2}{K_1 + K_2} \sqrt{\frac{\left(\frac{1}{R}\right)^2 + \left(\frac{1}{p\pi L} - p\pi K_0\right)^2}{\left(\frac{1}{R}\right)^2 + \left\{\frac{1}{p\pi L} - p\pi\left(\frac{K_1 K_2}{K_1 + K_2} + K_0\right)\right\}^2}}$$

$$V_0 = E \times \frac{K_1}{K_1 + K_2} \sqrt{\frac{(p \,.\, \pi \,.\, K_2)^2}{\left(\frac{1}{R}\right)^2 + \left\{\frac{1}{p\pi L} - p\pi\left(\frac{K_1 K_2}{K_1 + K_2} + K_0\right)\right\}^2}}$$

$$V_2 = E \times \frac{K_1}{K_1 + K_2} \sqrt{\frac{\left(\frac{1}{R}\right)^2 + \left(\frac{1}{p\pi L} - p\pi K_0\right)^2}{\left(\frac{1}{R}\right)^2 + \left\{\frac{1}{p \,.\, \pi \,.\, L} - p\pi\left(\frac{K_1 K_2}{K_1 + K_2} + K_0\right)\right\}^2}}$$

I will not enter into a general discussion of these equations, but will consider a particular case numerically, taking values in practical use as a starting point which apply to the diagram constructed for this purpose. I observe further that the relation of L to R and of K_0 to K_2 is given by the general design to the transformer and cables used; while the relation of K_1 to K_2 depends on the lengths for the particular case and other dimensions of the network.

* R is really not a constant quantity, as the energy used for magnetising and demagnetising the transformers cannot be put proportional to the square of the volts V_0.

For example, let the frequency be 43 ∽, then $p\pi = 270$, and let E = 2,000 volts, R = 10,000 ohms, $L = 10 \times 10^9$ C.G.S. units, $K_1 = 50$ microfarads, $K_2 = 1{\cdot}0$ microfarad, $K_0 = 0{\cdot}4$ microfarad. These values represent a network of a total length of about 85 kilometres of between 25 and 250 square millimetres cross-section, to which network is coupled a section of cable 1-2 kilometres long containing transformers of about 20 kilowatts output, with no secondary load. Fig. 4 gives the diagram of the voltages and currents which can be constructed on the above assumptions, and which represents the formulæ given above.

The current circulating in the resistance R (I_R) is in the same phase as V_0, and the current (I_1) representing the self induction is 90deg. behind V_0: the current through the condenser K_0 (I_0) is 90deg. ahead of V_0. The total current I is the resultant of I_R I_L and I_0, displaced from V_0 by an angle ϕ. The voltages V_1 and V_2 are 90deg. behind the current I; and the resultant electromotive force E, resulting from the combination of V_0 V_1 V_2 is displaced by an angle ψ in phase from the resultant current I. Looking at Fig. 4 we see that $V_0 \cos \phi = E \cos \psi$, whence we note that the greater the angle ϕ (that is, the greater the displacement of phase in the system $T_2 K_0$, and the smaller the angle ψ, the greater can V_0 and $(V_1 + V_2)$ become relatively to E—that is to say, the greater can the pressure become on the insulating material of the cable for the same voltage on the dynamo. The pressure $V_1 + V_2$ divides itself in the inverse ratio of the capacities K_1 K_2 on the two condensers, that is to say, the higher and dangerous pressure comes on that piece of cable which has the smaller capacity;

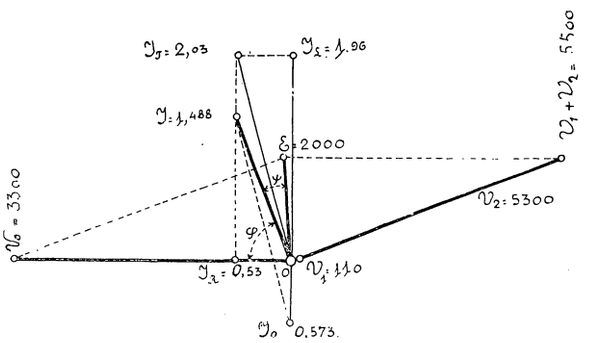

Fig. 4.

in most cases, therefore, on the part of the network which is being switched in or out. The greater K_1 becomes in relation to K_2 the greater becomes V_2 in relation to V_1, but when K_1 become much larger than K_2, the ratio V_2/V_1 rises very slowly, even if K_1 becomes very much larger. Thus when the section of the network already working is very extensive, the addition of another portion becomes of less importance and has less effect. For a certain length of the cable switched in (K_0 K_2) there is a certain number of transformers (R L), for which the ratios $V_0 : E$ and $V_1 + V_2 : E$ become maxima.

The calculations I have taken as an example under the above assumptions gave for V_0 and V_2 pressure of 5,300 and 5,390 volts, with a generator supplying current at 2,000 volts; and on the assumption that the dynamo furnished currents and volts which followed substantially a siné law. These cases are not very common in practical dynamos; on the other hand, there are cases in which the departure from a sine law is so great that a relatively much higher rise of volts can take place than in the case just considered. Further, a rise of volts can also take place for this reason, that the iron cores of the transformers become more saturated on account of the rise in volts. Apart from these latter considerations the "theoretical" values of V_0 and V_2 represent by themselves pressures which would be a source of danger to the cable network and the transformers coupled to it, and which as experience has shown are large enough to be a source of breakdown in cases in which the factors happen to have the right ratio to one another.

To avoid this undesirable rise of volts a rule must be made that the inner conductor must never remain coupled on alone in cases where the switching arrangements, are not so constructed as to make a mistake impossible.

ELECTRIC SIDE-LIGHTS ON SHIPS.

In the Departmental Paper No. 176, recently issued by the Board of Trade, the use of powerful glow lamps in the red and green side-lights for ships is discussed. The following Memorandum by Sir Digby Murray relates to the green lights, and a further communication has been made by him on tests of the red lights. It is found that the electric light has the effect of somewhat paling the red light, but red slides of the darker of the two standard tints, or of a shade intermediate between the two standards, are found to give a very good colour.

In consequence of the representations of the Russian Naval Attaché as to the effect of the electric light on the green side-light of the Russian Imperial yacht, I promised to thoroughly investigate the subject. I requested Mr. Samson to make some initial inquiries and experiments, and as these latter appeared to show that the electric light did, to a certain extent, neutralise the colour of the green slide or lens (as the case may be), I determined to thoroughly experiment with a view to ascertaining definitely the effect of the electric light of different degrees of intensity on the green glass. Hearing that Sir Donald Currie and Co. applied electric light of very considerable candle-power to their side-lights, I wrote to that firm requesting that they would give Mr. Samson facilities for inspecting their lights, and it is owing to their kindness and courtesy and the able assistance rendered by their staff that it has been possible at once to arrive at a solution of this question. The Board of Trade sent their standard side-lights, together with the standard green slides as approved by the Admiralty and the Board of Trade, to Sir Donald Currie's office at Blackwall, and at 8 p.m. of Wednesday, November 2nd, the trials took place before Captain Rogestvensky, the Naval Attaché to the Imperial Russian Embassy, Mr. Samson, and myself, and were of the most conclusive character.

The lamps tried were three in number, viz. :—

1. An electric side-light manufactured by Messrs. Chance Brothers, of Birmingham, having a green slide of a different colour and deeper tint than the darkest shade of the two Board of Trade standard colours.
2. An electric side-light, having a green slide of the same tint as the darker of the two Board of Trade standard colours.
3. The Board of Trade standard oil lamp, having a green slide of the same tint as the lighter of the two Board of Trade standard colours. I was anxious to replace this slide with one of the darker tint; but our spare slides would not fit this particular lamp, and, as our experiments subsequently showed, this was not material.

It was raining during the time the experiments were being carried out, but this did not at all affect the comparisons between the three green lights, although it considerably affected the colour of the white mast-head light, giving it a reddish tinge. The electric side-light of Messrs. Chance showed a good colour throughout the whole of the experiments; though the green slide of this lamp was of a deeper colour than the darkest of the Board of Trade standard tints, there was only a very slight perceptible difference between its colour when lighted by electricity and the colour of the oil lamp which had a slide of the lightest of the Board of Trade tints.

The conclusions Mr. Samson and I have arrived at are as follows :— In the case of electric side-lights neither of the standard greens are dark enough, and the colour should either be determined by experiment, in which case the colour of the side-light at the particular candle-power it is intended to use should not show lighter than that of a full-sized oil lamp fitted with the lightest of the two standard tints of green, or the shade of colour which Messrs. Chance have in consultation with Sir Donald Currie and Co. manufactured for this particular lamp on board the "Roslin Castle" should be adopted. We think it desirable that a number of slips of glass of this colour should be obtained from Messrs. Chance for the information of the Board's officers, and through them of the shipowning public, and that a cautionary circular should be sent out to the surveyors to the following effect :—

> "It having come to the knowledge of the Board of Trade that the two standard green tints adopted by them for oil lamps are not applicable to electric side-lights, surveyors are informed as follows :—
>
> "In the case of electric side-lights neither of the standard tints of green are dark enough, and the colour should either be determined by experiment, in which case the side-light should not show of a lighter colour than that of a full-sized oil lamp fitted with the lightest of the two standard tints of green glass, or the shade of colour which Messrs. Chance have adopted in consultation with Sir Donald Currie and Co. in the starboard side-light of the 'Roslin Castle' should be adopted.
>
> "Samples of these glasses are forwarded herewith, and surveyors should make this information as public as possible."

We append a table showing the experiments :—

Description of Light.

Starboard electric side-light with a specially dark-tinted slide, by Messrs. Chance Brothers.	Starboard electric side-light with a slide of the darker tint of the two Board of Trade standards.	Board of Trade standard starboard side-light, burning mineral oil with a slide of the lighter tint of the two Board of Trade standards.
16 c.p.—Good colour	Pale in colour.	Very good colour.
32 c.p.— do.	Too pale in colour.	—
50 c.p.— do.	do.	—
100 c.p.— do.	Not tried.	—
200 c.p.— do.	do.	—

All the electric lights were incandescent lights. As compared with the oil lamp fitted with the light green slide, the electric light fitted with a slide corresponding to the darker standard green was too pale, and with 32 and 50 c.p. was nearly white. Messrs. Chance's light, though fitted with a specially dark slide, showed only just a shade darker colour than the oil lamp. The difference in candle-power did not seem to further affect its colour, *i.e.*, its colour with 200 c.p. was as good as with only 16 c.p.—(Signed) DIGBY MURRAY, PETER SAMSON.

ON TESTING AND WORKING ALTERNATORS.*

BY W. M. MORDEY.

(Concluded from page 516.)

Power Factor of Alternating Motors.

The "power factor," or "plant efficiency," of alternate-current motors, whether synchronous or not, is a subject of great importance, on account of its bearing on the economics of power transmission by alternate currents. Although at the moment the power factor of motors is not as pressing a matter as the power factor of transformers (which has received Dr. Fleming's recent attention), it is desirable to find whether for alternate-current motors we have to use cables and machinery capable of carrying a large idle current, or whether we can treat power-transmission projects, so far as these matters are concerned, in the simple manner that is possible with alternate-current transmission with good closed magnetic circuit transformers. I am able to say that, so far as my own observations go, working with one class of alternators, the power factor of these machines when used as motors under fair loads is very high, if they are used under conditions that are easily obtained.

Fig. 6 illustrates the way in which the load-factor varies with the excitation. The two V-shaped curves show the current that was taken respectively by an "A 7" 25-kilowatt alternator, and by an "A 10" 50-kilowatt alternator, running as motors, without

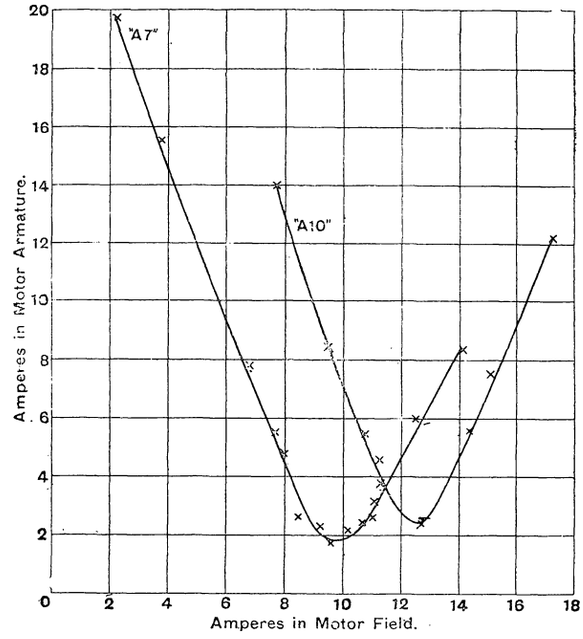

FIG. 6.

load, when the excitation was varied. They were driven by another alternator, and a potential difference of 2,000 volts was maintained across the terminals. Speed constant at 100 ∿. It will be observed that in each case there is an excitation that reduces the armature current to a minimum, and therefore gives a maximum power-factor and maximum efficiency. If the excitatiou is varied on either side of that value, the armature current rapidly increases. In order to find whether the same kind of effect takes place when the motor is loaded, one of the motors was made to drive another alternator the load on which was varied. It was found, as was to be expected, that with various loads, and of course at constant speed, there was for each load an excitation that corresponded with a minimum armature current; that the armature current rose on varying the excitation either up or down, and that the excita-

* Paper read before the Institution of Electrical Engineers, February 23, 1893.

Hosted by Google

tion that gave the lowest armature current (or the highest efficiency and highest power-factor) was approximately the same for all loads, with the same impressed potential difference.

This is what one would expect. With a weak field a large armature current is required to give the necessary torque; while with a strong field the E.M.F. of the motor is higher than that of the generator; the driving current, therefore, is large for a given torque, as it cannot get in advantageously. It will be remembered that Dr. Hopkinson predicted years ago that an alternator would run as a motor under the condition of the motor having a higher E.M.F. than the generator.* From these curves we see that the power-factor may vary enormously, but there is no difficulty in making it a minimum and the efficiency a maximum by always working at the excitation that gives the lowest reading of current. It will be seen from the table of results given above that the power-factor is high. It appears to fall away at no load to a much lower value, as will be seen from an examination of the two curves. This, however, is of no practical moment, as the machines do not take much to drive them under light load conditions; and although I have not made determinations at intermediate points, it appears that, as was shown by Dr. Fleming to be the case with closed-circuit transformers, the power-factor approached unity as soon as load was put on. It is satisfactory to find that, in this respect, these two classes of alternate-current apparatus have similar qualities.

The present opportunity may be taken to allude to a device which I have used for some time in connection with the working of alternators, and which we apply to all the larger machines. In alternator armatures there are advantages in having the coils arranged in two or more parallel portions, instead of all in series. The insulation of the terminal portions of the winding is easier, and, except in small machines, the conductors are more manageable. But in practice we have found that the parallel arrangement has one drawback. Unless the coils are equally and simultaneously acted on all round, the voltage of the two portions will not be

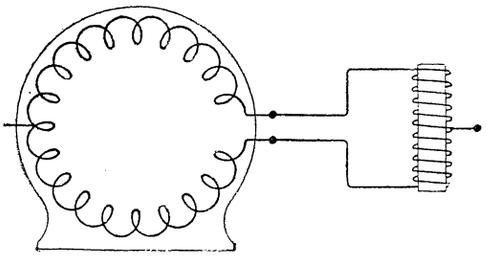

Fig. 7.

equal, and a circulation of current will take place within the armature. The machine will, in fact, act to some extent as in the dynamotor method described, and a loss of power will result. This has probably been overlooked in machines having revolving armatures, as with such armatures it is not easy to observe the effect. It is difficult to avoid this circular current by ordinary means. If the pole-faces are exactly alike in size and position, and the polar gap is the same all round, and the armature coils are identical in winding and in relative angular position, the inequality will not exist. But these are conditions that can only be certainly obtained at a considerable expense. With cast magnets the poles vary a little. The armature coils are adjusted radially, and it would be troublesome and expensive to place them so as to comply with the conditions mentioned. By a simple application of a known property of transformers this difficulty is avoided. This is shown in Fig. 7. A pair of similar coils is arranged in the manner of a transformer, one coil being placed in each half of the armature circuit. The connections are such that with equal currents from the two portions of the armature there is no magnetism induced, the two windings neutralising one another. But any tendency of one portion of the armature to give a larger current than the other portion is resisted by the "equaliser" (as I term this apparatus), which then acts as a transformer opposing an E.M.F. in the circuit which has an excess, and adding a corresponding E.M.F. to the circuit of lower voltage. Thus the two portions of the armature contribute equally to the external circuit, while the circular current is prevented, whether on open circuit or under load. The equaliser is quite a small affair. As an example of its efficacy, I may mention that in one case the two sides of a 250-kilowatt 2,000-volt alternator were made so unequal that a current of 16 amperes circulated. The addition of a small "equaliser" reduced this circular current to half an ampere.

I do not know whether this inequality has been noticed by others, but it is well known that it may exist in direct-current dynamos when different parts of the armature are acted upon unequally, and it has been cited as an objection to the paralle winding and connection of armatures in such machines with multipolar fields. Whatever force there may be in this objection, it will be granted that it is not as easily met as in alternators. Indeed, it may be said of alternate-current apparatus generally, that, although difficulties are met with, and often of an unexpected kind, their very nature provides us with new and simple means of avoiding or reducing them. In iron-cored armatures, whether of alternators or dynamos, the iron core may to some extent tend to counteract inequalities of this sort.

Parallel Working of Alternators.

This subject has received a great deal of attention during the last few years. I do not desire to add anything to the literature dealing with its theoretical aspects, but, as it may be of interest to some members of this Institution, I take the opportunity of giving a description of the principles on which my colleagues and I act in dealing practically with parallel working. Some years ago Mr. Raworth and I recognised that this was quite as much a question of prime motors as of electrical apparatus, and we then settled on the main points of the arrangements for parallel working, which have been acted on ever since, practically without change. 1. Each alternator is driven by a separate engine. 2. All the engines are in parallel on the steam-pipe, and are supplied with steam at the same pressure. 3. All the alternator fields are magnetised in parallel, and are supplied with current at the same pressure. 4. All the alternator armatures are in parallel, and supply into the mains at the same pressure. 5. Each alternator gives its proper proportion of load by regulation of the amount of steam admitted to its engine. 6. The regulation of potential difference is by the control of the common exciter.

Thus it will be seen that the individual regulation of current (that is, of load) of each alternator is entirely by control of the steam supplied to its engine. The regulation of the E.M.F. as a whole is by the control of the excitation simultaneously affecting all the alternators. Each engine must be capable of control when working, either by the stop-valve or by having a governor capable of adjustment when running.

In working alternators in parallel the precautions that should be observed will be best understood by a consideration of the following:—Consider the case of two alternators. Assume that one alternator, A, is running and doing work driven by its engine, E, and that it is required to start the second alternator, A_1, with its engine, E_1. Start the engine E_1 and excite the alternator A_1. If the fields of the alternators are excited in parallel from the same exciting source—as is preferred, and as we arrange whenever possible—there is no necessity for any adjustment of the individual excitation (except for differences of temperature). It is merely necessary to connect the field to the exciter. It will then receive the proper field current. Let the double-pole main switch of A_1 be open. The synchroniser is then to be switched on, and the speed of the engine E_1 adjusted till the synchroniser lamp is steady, showing that the alternators A and A_1 are running at the same speed. It will not be found difficult to so adjust the engine E_1 that the synchroniser lamp shall remain steady for several seconds at a time. For greater accuracy a voltmeter may be used instead of or in addition to the synchroniser lamp. When the synchroniser lamp (or voltmeter) is at its highest, the double-pole main switch of A_1 should be closed, so connecting the alternators in parallel. It will be perceived that at this time the engine E_1 is only supplied with steam sufficient to drive the alternator A_1 (without load) at the required speed. The alternators when put in parallel will therefore merely keep in step, A_1 doing no work on the external circuit and receiving no power from that circuit. This will be shown by its ammeter, which will show that no current, or only a very small current, passes between the machines. As the supply of steam is increased, the ammeter of A_1 will show an increased reading, while that of A will show a decreased reading, until (in the case of alternators of the same size) the two instruments show that the load is equally divided between the machines. When this condition is attained no further regulation of engines is required, any increase or decrease of load dividing equally between them. The control of E.M.F. is effected by regulating the exciter, and not by means of resistances in the field circuits of the alternators. As the fields are all wound to excite from the same mains, there is no need for an individual regulation of the fields, except, perhaps, a slight adjustment to compensate for difference of temperature between machines that are being started cold to work with others that have become warm by long running. The field ammeter should be observed in order to give each machine the same excitation.

To stop one alternator when two or more are running, the load should not be switched off suddenly, but steam should be gradually reduced by the governor or stop-valve of the engine until the alternator is doing no work, as shown by its ammeter. Then the switch between the alternator and mains should be opened and the engine stopped. If the steam is gradually reduced in this way, the load

* *Journal*, Vol. XIII., p. 505, November, 1884.

Hosted by Google

will be transferred to the remaining engines and alternators before the machine is switched off, and no racing of the engine can occur. Steam should be turned off till the ammeter needle goes back to zero, showing that the alternator is not doing any work. If steam is continued to be turned off beyond this point, the alternator will then *take* current (to drive it as a motor and to enable it to drive its engine), and the ammeter needle will, after going back to zero, show a deflection representing this received current.

It may, perhaps, be pointed out that artificial loads need not be used in putting alternators in parallel. This is sometimes done, but it can only be necessary where the characteristics of the machines show great variations between no load and full load.

In conclusion, I have to thank the Brush Company for the preparation of the diagrams; and my hearty acknowledgments are due to Mr. Woof and Mr. Watson, two of the company's heads of works departments, and to Messrs. Stobart, Hansard, and Foyster, students and assistants, for much careful and willing assistance in carrying out trials by these methods.

[*An abstract of the complete discussion on this Paper will be given, probably next week.*]

THE LIGHTING OF BELFAST.

On Thursday last Prof. A. B. W. Kennedy's report on the proposed public lighting of Belfast was submitted to the Gas Committee of the Belfast Corporation. Prof. Kennedy states that, having had an opportunity of carefully examining the streets and buildings, and the several proposed sites for a central lighting station, he finds he cannot recommend any one of the ordinary systems in use without important modification, and he therefore, in his report, gives the Corporation separate figures connected with the proposed central and southern districts of lighting, as it is probable that the Corporation will proceed sooner with the lighting of the former than the latter district. It being impossible to obtain any definite data on which to base an estimate of the amount of current likely to be required, Prof. Kennedy has prepared his own estimate, based upon his examination of the City, and his experience in other districts. He thinks it probable that within two or three years of starting the works Belfast will require a current equivalent to 8,500 lamps of 8 c.p. in the central district, and in the southern district about 4,000 similar lamps, and he thought that provision would be ample if made for rather over 6,000 lamps in the first case, and for about 1,400 lamps in the second. Basing his estimate upon these calculations, and taking the charge per unit at 6d., the income per lamp in the central district would be 8s. 9d. per annum, and in the southern district 5s. 9d. per annum. On the assumption that about 17·5 units per annum would be used in the former district, and about 11·5 units in the latter, the total income would be £3,850 and £1,200 respectively, with a reasonable probability that in the former case the amount would be much larger. The central business part of the city is of small extent, comprising all the scheduled streets which contain first-class shops and business premises, clubs, banks, and other similar buildings. This is the sort of district in which the electric light is generally most popular, and where it has paid best, as there is no difficulty in supplying the light economically. For this district Prof. Kennedy recommends putting down a low-tension network of distributing mains; this is equally essential whether the current be originally generated at high or low tension pressure. Prof. Kennedy carefully reviews the special features observable in the case of Belfast, where one portion of the city is occupied by business premises, and another portion is entirely residential. He points out that for the latter it would be necessary to make a considerable expenditure, without any reasonable expectation of an early profitable return, and, in the result, suggests that the residential districts of Belfast should be omitted from the electric lighting scheme until such time as the demand for the light justifies its extension beyond the boundaries of the business portion of the city. The southern district could most cheaply be supplied with electric energy by a high-tension alternating current sub-transformer system, but that unfortunately there does not seem to exist (except on paper) any satisfactory way of cutting these transformers out of circuit when not in use, the result being that the loss is so considerable that he recommends the Corporation to spend an additional £1,500 in laying low-tension distributing mains in this district also, so that both the Central and Southern districts will be supplied in a similar manner. With regard to the site for a central station, two of those recommended have special advantages, and either of which would serve perfectly for generating high-pressure current; one is called the Ormeau-avenue site, the other the Albert Bridge site, and both belong to the Corporation. The riverside station would be out of the question for a low-pressure system, which would be considerably most costly than any other, the excess of cost being greater that Prof. Kennedy feels justified in recommending the Corporation to incur. In places like Belfast, where the day load is always very small, and where the difference between summer and winter lighting is much greater than the average, it is of special importance to economise both labour and fuel at times of low load, and the most practicable method of doing so in this case is by the use of batteries, and Prof. Kennedy has endeavoured to scheme out a system by which may be gained the advantage of the use of batteries at a cost very much less than that of a direct three-wire system worked from one central station in the usual way. This could no doubt be done on the Oxford system, but when worked out the expense appeared to be as great in the case of Belfast as that of an ordinary direct-current system. Prof. Kennedy therefore recommends the Corporation to adopt what he considers the most economical and advantageous form of sub-station, viz., one in which the dynamo or dynamos are driven by ordinary gas engines, using town gas (in Belfast 2s. 3d. per 1,000 cubic feet). This central sub-station should be used in a quite different fashion from the ordinary sub-station. It should be the head-quarters of the system of distribution, and would probably contain two gas-engines of about 50 I.H.P., with corresponding dynamos, and a battery installation of about 500 ampere hour capacity, so that the plant would be always at work when it was necessary for any machines to be running at all; it would be connected with the central station simply by a pair of trunk mains, and would not contain any special reserve plant, as in case of failure of any machine, the necessary additional current could be sent through the trunk mains from the central station without any disturbance of pressure in the distribution. By adopting this suggestion the whole of the plant of the central station would not always be at work; the gas engine would allow its machinery to be started at any moment if required, and even in the winter would only necessitate having one watch per day. The central station would contain plant for taking up three-fourths of the load, together with all reserves, as experience proves that the entire plant would only be required for a few hours, and always at times well known beforehand. From figures supplied of the gas demand it was probable that for three or four months in the year it would not be necessary to run the central station at all, as the small sub-station would be quite sufficient to generate all the current required. By this means the work could be carried on all the year round, in spite of the varying load, with the greatest economy in respect to wages and to wear and tear of plant. This system would necessitate the use of gas engines in both the cent al and sub-stations, as this would obviously be the most economical power under the circustances. One of the chief difficulties, and one which has put the use of gas engines out of the question in many cases, is the size of engine required. This difficulty does not exist in the case of Belfast, as no engine of more than 100 I.H.P. would, at any rate for the present, be necessary, and this fact has weighed very much with Prof. Kennedy in forming his decision. He is fully aware that great difficulties still exist in arranging that dynamos shall be driven direct by gas engines, but this has been done on the Continent, and may, consequently, be done at Belfast, but if unsuccessful it may be necessary to face the disadvantages of belt or rope driving. He does not feel himself able to recommend the Corporation to use generator gas, as this system is still only on its trial, more particularly in connection with work so irregular as electric light work; its first cost is great, while the cost of plant necessary in the gas-engine system which Prof. Kennedy recommends is small. The southern, or smaller district, would only require about 100 I.H.P. altogether, of which one-half might be placed in 25 H.P. units in, say, two sub-stations, and the remainder in the central station. The sub-stations would be connected with the central station, as in the case of the central district, and in such a way that the latter would serve as a reserve in all emergencies, and could also supply half the required power at the heaviest load.

The distributing mains would be connected through to the central district, so that the batteries would keep the mains always alive, and supply the small amount of current for 18 hours out of the 24 for the greater part of the year.

Summing up, Prof. Kennedy estimates the cost of the scheme which he recommends, exclusive of lands, buildings, and meters, but including the whole of the plant, mains, and road work, at about £19,000 for the central or larger district, and for the southern, or smaller district (including nearly double the amount of road work necessary for the larger district) about £11,000, including, as in the former estimate, all plant and machinery, mains and roadwork, but omitting buildings, lands, and meters. In the case of the central district the expenditure, to a certain extent, may be made dependent on the demand for light. The mains must be laid down at once, and represent about half the total outlay; but if the immediate demand for the light were smaller than estimated the plant at the central station could be reduced until the demand increased, which Prof. Kennedy does not think would be very long. In carrying out the lighting of the smaller district the Corporation would, of course, proceed step by step, commencing with the sub-station nearest the central, and where houses are closest together.

Prof. Kennedy estimates the actual station expenses, including salaries, wages, gas, stores, and repairs, at about one-half the price per unit, viz., 3d.—that is, when there are about 8,000 lamps wired. Other expenses, such as management, rent, rates and taxes, interest, sinking fund, and depreciation, would add a further 3d. It would seem, therefore, not unreasonable that the charge made at the start should be 7d. per unit, which would decrease as the number of units sold increased.

PARLIAMENTARY INTELLIGENCE.

HOUSE OF COMMONS—TUESDAY, MARCH 7.

HAMPSTEAD, ST. PANCRAS AND CHARING CROSS RAILWAY.

A Committee of the House of Commons, presided over by Sir C. Dalrymple, sat on Tuesday to consider the Hampstead, St. Pancras and Charing Cross Railway Bill. Mr. Pembroke Stephens, Q.C., Mr. Hume Williams and Mr. Le Breton appeared as counsel for the promoters, and the opponents of the Bill were the Vestry of St. Pancras (represented by Mr. Castle, Q.C.), the British Medical Association (by Mr. Meysey Thompson, Q.C.) the St. Giles District Board of Works (by Mr. Courthope Monro), the London County Council (by Mr. Freeman, Q.C., and Mr. Cripps, Q.C.), and the Vestry of St. Martin's-in-the-Fields (by Mr. Claude Baggalley).

Mr. PEMBROKE STEPHENS opened the case for the Bill. The feature of the scheme was, he said, that the line would be made in two

Hosted by Google

tunnels, which would ensure good ventilation and the avoidance of smoke and sulphur. The system under which they proposed to work was the cable system, with electricity in reserve, so that whichever was found to be the safest system would be adopted. The learned counsel referred to the report of the Joint Committee of both Houses of last year, which adopted conclusions in favour of the sufficiency and special adaptibility of electricity as a motive power for underground tubular railways, while they also regarded cable traction as of recognised utility, especially in the case of steep gradient lines. The proposed line would have a steep gradient nearly the whole way, and, therefore, the promoters proposed to test the cable system as a primary one; but they also included in the Bill power to use electricity in case it should hereafter be found to be the more desirable mode. He explained that the line had been somewhat altered from that which was projected last year, inasmuch as the St Pancras portion of it, which was originally intended to pass under St. Pancras Station and terminate at King's Cross, had been shortened to meet the wishes of the Midland Railway Company, who were naturally sensitive with regard to the effect which might be produced on the large pile of buildings which constituted their station and hotel. The capital of the company would be a million and a-half, with one-third that amount borrowing powers.

Mr. GREATHEAD, engineer to the Company, explained the plans to the Committee, and the method of construction, and said that communications could be easily made by means of subways with Euston Station and the South-Eastern Station, at Charing-cross. The line could be worked either by the cable system or by electricity, and he did not think there was much to choose between them. It was proposed to establish the motive power opposite the North London Station at Chalk Farm, which would be a very convenient and suitable site for a generating station.

Mr. HENRY CLARK, of the London County Council, a resident of Hampstead, and Mr. D. C. NICHOLS, an architect and surveyor, gave evidence in support of the Bill, and the main opposition arose with regard to the premises of the British Medical Association in the Strand, which the Chairman declared to be a matter of clauses. The preamble of the Bill was proved, and the Committee adjourned, but on the Wednesday spent a short time in adjusting the clauses for the protection of the British Medical Association, and the Committee then ordered the Bill to be reported to the House for third reading.

THURSDAY, MARCH 9.

THE BARRY ISLAND ELECTRIC RAILWAY BILL.

The Barry Railway Bill, one object of which is to construct a railway to be worked by electricity, came before a Select Committee of the House of Commons, presided over by Mr. Stephen Williamson. All appearances being withdrawn, and there being no opposition, the Bill was referred to an unopposed Committee.

LEGAL INTELLIGENCE.

Alabaster and Others v. Medical Battery Company (Limited).

This case came before Lord Coleridge and a special jury in the High Court of Justice on Tuesday last. It was an action by the proprietors of the *Electrical Review* for an injunction restraining the defendants from continuing to disseminate a circular alleging that the *Electrical Review* had published "malicious libels" concerning the Medical Battery Company and Electropathic and Zander Institute, and claiming damages. The defence was a plea of privilege.

Mr. Finlay, Q.C., Mr. Lawson Walton, Q.C., and Mr. Bankes were for the plaintiffs; and Sir Edward Clarke, Q.C., and Mr. R. A. Germaine for the defendants.

Mr. FINLAY, in opening, said the libel complained of was in respect of a circular sent out by a solicitor on behalf of the Medical Battery Company, which substantially belonged to Mr. C. B. Harness, to a large number of newsagents. That circular read as follows:—

"39, Hatton-garden, London, E.C., September 16, 1892.

"SIR: Having been consulted by my clients, the Medical Battery Company (Limited), the proprietors of Harness's Electropathic Belts, and also the Electropathic and Zander Institute, of 52, Oxford-street, W., with reference to some malicious libels published in the *Electrical Review* and a paper called *Science Siftings*, I beg to give you notice that if these or any further publications containing defamatory articles or paragraphs are sold or circulated by your firm, my clients will hold you responsible. In the same way you will be held responsible for the exhibition of any libellous bills or placards.—I am, Sir, yours obediently, AUGS. FLEET."

The answer of the defendants to the action now brought was that the circular was sent out to newsvendors in self-defence, and with the view of founding possible proceedings against those newsvendors. As a matter of law, he submitted, the plea of privilege in this case was an absolutely false one, and the jury would be able to form their own opinion as to the *bonâ fides* of that defence. The Medical Battery Company was a very extensively advertised firm, established for the purpose of selling what were known as electropathic belts. The patients had their choice of belts at different prices, and were recommended to wear them with the idea of being cured by currents of electricity, no matter what was the nature of the diseases from which they were suffering. This system of business carried on by the defendants was brought prominently to the attention of the plaintiffs by an action which was tried at the Bloomsbury County Court on July 19, 1892. A man named Jeffery had been suffering from hernia, and went to the Institute of the defendant, where he was persuaded to buy an electropathic belt for £5. 5s. He was only able to pay down the sum of £2, and the defendants had the assurance to sue him for the balance of £3. 5s. The case was fully investigated, Mr. Gatehouse, one of the plaintiffs, gave evidence on behalf of the defendant, and stated his opinion of the belt. Judgment was given for the defendant on the ground that the belt was absolutely useless, and the Medical Battery Company were directed to return the £2 which the poor fellow had been induced to pay on account. That was how Mr. Gatehouse first came to close quarters with the Medical Battery Company A report of the case, and also an article upon it, appeared in the *Electrical Review* for July 22nd. The article strongly condemned the practices carried on upon the premises of the Medical Battery Company, and said that if ever there was a matter demanding the immediate attention of the Public Prosecutor, the revelations made at the Bloomsbury County Court pointed to it. It was stated in the course of that case that the "hernia specialist" in the service of the Medical Battery Company had been at an earlier period in his career a furniture salesman. Subsequently the articles appeared in the *Electrical Review*, some of the most recent commenting upon descriptions which had appeared in other papers of Harness's Institute.

Mr. GERMAINE said Mr. Finlay had not accurately grasped the issue before the jury. On the pleadings there was an entire absence on the part of the defence of any justification whatever. Any question as to the efficiency, utility, or uselessness of the belts was not in issue in the case. If the defendants had intended to raise it they would have pleaded justification.

The LORD CHIEF JUSTICE: It all goes to the question of damage.

Mr. GERMAINE said there was an action pending in which the question of the efficacy of the belts would be gone into fully.

The LORD CHIEF JUSTICE: Possibly this case may save all that (laughter).

Mr. FINLAY said he would not waste time in dwelling upon the serious nature of the accusations against Mr. Alabaster, Mr. Gatehouse and the other managers of the *Electrical Review*, namely, that they had prostituted their position as editors of a scientific journal for the purpose of publishing malicious libels. If they had done this they would deserve to be exposed and condemned by every honest man But that was, in fact, the allegation the defendants thought fit to make with regard to these gentlemen. They sent round the circular to hundreds of newsvendors regardless of the fact whether they happened to sell the *Electrical Review* or not, and the result was that the plaintiffs were inundated with applications for indemnities relieving the newsvendors from responsibility. One large firm refused to sell the journal on any terms. Accordingly the writ for the present action was served on September 22nd, and the excuse set up by the defendants for the purpose of justifying so serious an attack upon the personal character and professional honour of the plantiffs was that they were acting in self defence. In order to show the shallowness of the defence counsel called the attention of the jury to the kind of proceedings that went on at the Institute and the character of the goods sold to an unwary public. A pamphlet had been issued by the defendants, containing the most formidable list of disorders counsel had ever seen. It was entitled "The Medical Uses of Electricity; a Treatise on the Electropathic Method of Curing Disease," by Mr. C. B. Harness, consulting medical electrician, President of the British Association of Medical Electricians, Member of the National Electric Medical Association, and Member of Honour (with Cross of Merit) of the Belgian Society of the Red Cross, &c., &c. The names of Sir Charles Locock, Sir Henry Holland, and Sir William Fergusson, Physicians to the Queen, were given in the pamphlet as advocating electrical treatment for the cure of disease. He (Mr. Finlay) was aware that there were diseases where electricity would prove beneficial. But as to the belts sold by the Medical Battery Company, could a person with the most elementary knowledge of electricity suppose they could generate electricity in the body at all? The belts contained discs of zinc and copper. An extremely minute quantity of electricity would be generated when the zinc and copper discs were worn upon the body, and the discs connected externally; but unless there was a connection there could be no current, and he would call evidence to show that belts had been sold at the Institute for such sums as five guineas, ten guineas and more, when it was absolutely impossible that there could be any current of electricity whatever. Even assuming there was an external connection—and Mr. Harness had recently been telling people there must be this connection—the current would be excessively feeble. By far the greater part of it would return, not through the body, but would pass through the webbing of the belt round the body. In dealing with the question of the *bonâ fides* of the attack made by the defendants upon the plaintiffs he would ask the jury to bear in mind these two facts—first, that the defendant Harness was in the habit of selling belts with the external connection, and secondly that even if an external connection were made the current of electricity generated would be so excessively feeble that for all curative purposes it would be absolutely worthless. He did not think he was exaggerating when he said they could get more electricity out of a pin and a needle dipped in ink than out of one of these electric belts even if properly connected. The jury would have materials laid before them which would satisfy them beyond all doubt that the defendants were seeking to stifle what they must have known or suspected to be well deserved criticism by endeavouring to stigmatise that criticism as a malicious libel.

Mr. W. Timbrell, Mr. Catlin, Mr. Vickers, Mr. Hughes, Mr. Allen, Miss Davis, and other newsagents, Mr. A. J. Godstall (from Messrs. W. H. Smith and Son), and Mr. H. Tourle (from Messrs. Simpkin, Marshall, and Co.), all gave evidence as to receipt of the circular, and of declining to continue the sale until given an undertaking to indemnify them by the plaintiffs.

Mr. FRANCIS REEVES, an electrician, carrying on business at Mansion House-buildings, said he knew Mr. Harness, the Managing Director of the Medical Battery Company. Mr. Harness told him that 500 circulars had been sent out to newsvendors.

Hosted by Google

Cross-examined by Sir EDWARD CLARKE: At the time of these conversations they were either travelling by train or standing on the platform. They lived at the same place. He was not a friend of Mr. Harness's—only a railway acquaintance.

Mr. BANKES was about to call Mr. Jeffrey as a witness, when

Sir EDWARD CLARKE took exception to evidence being called as to the utility of the belts. Such evidence, he contended, was not admissible on the issues on the record. Having quoted cases bearing on what he averred was the real issue, the question of privilege, and the necessity of notifying newsvendors as to libels which they might disseminate. The only defence put upon the record was one of privilege. The defendants had an action pending against Messrs. Alabaster, Gatehouse, and Co., and in fairness they gave notice to the persons who might be selling the libel. The question as to the efficacy of the belts would be raised in the other trial, which would come on at an early date, and the proper course would be to leave that issue to be tried in that action, where it was the real issue.

The LORD CHIEF JUSTICE held the evidence to be admissible, and said the issue was clearly raised on the question of *bonâ fides*.

Sir EDWARD CLARKE then applied that this action might be allowed to stand over or be consolidated with the other action, in order that the whole question might be gone into, and have a final and effective determination. His clients would consent to any terms as to costs.

Mr. FINLAY opposed the application, and said the action of the Medical Battery Company was not brought until after the present action was instituted. They knew very well that the issue would be raised in this case, for it was quite impossible to suppose that the defendants did not appreciate that the question of their *bonâ fides* in sending out the circular would be at issue.

The LORD CHIEF JUSTICE said the issue was very narrow. In his opinion evidence was relevant which raised the issue as to the *bonâ fides* of the plaintiffs in writing the articles and publishing them. The plaintiffs said their object was to expose scientific humbug. On the other side it was said that was not so, but that the articles were printed with the object of injuring the Company. He could not say such things could not be introduced.

Sir E. CLARKE: Then your Lordship does not think it right to adjourn upon any terms?

The LORD CHIEF JUSTICE: I have no right to do so. The matter seems to be properly raised, and therefore you should have been prepared to meet it. I cannot—because you have another action pending, which may or may not be prosecuted—adjourn this action.

Sir E. CLARKE: Then I am instructed by my clients to say we are not prepared to deal with the points which have been indicated in the opening of Mr. Finlay, and which they were certainly under the impression would not be raised. Therefore I shall take no part in any controversy if these witnesses are called. We are prepared to admit the libel, and that damages must be paid. The jury will be left to fix the damages on the question relevant to that issue.

Mr. FINLAY said the course taken by his learned friend brought the case to an early termination. It was a termination which he should think very few of those behind the scenes had not expected. Up to the present moment the defendants had shown a bold front. They knew that the attack upon the personal character and honour of the plaintiff was not made *bonâ fide*. The suggestion was put forward that the circular was sent out to the 500 newsvendors precedent to possible actions being taken against them. The circular was written without any object of the kind. It was sent round because Mr. Harness resented the criticisms which appeared about his Institute, and the way business was carried on there. He resented the exposure of the system, and he had thought fit to characterise the articles as malicious libels. The defendant knew perfectly well what he had to meet. He could not fail to have known it. He knew the witnesses who were to be called. Why was the defendant not prepared? It was not for want of time nor knowledge. Mr. Harness had the assistance of learned counsel. He had the assistance of his solicitors. The jury were asked to suppose it never occurred to these gentlemen that questions as to the honesty and good faith in making the attack would come into issue? Of course they knew it. Then why was Mr. Harness not prepared? He was not prepared because he would never be prepared to face such an issue. After a strong denunciation of the methods pursued by the defendants Mr. FINLAY asked the jury to mark their sense of their conduct by giving exemplary damages.

Sir EDWARD CLARKE said his learned friend had assumed his case had been established by evidence. That was not so. There was another case pending in which the plaintiffs were the Medical Battery Company and the defendants the owners of the *Electrical Review*. At the hearing of that case would be the proper time to go into the question of the belts being effective or non-effective. The question raised in the present case was whether the circular which had been sent out by the solicitor to the defendants was privileged, whether the sale of the paper had diminished, and whether the reputation of the plaintiffs had been injured. As a matter of fact the plaintiffs had not suffered at all. The circulation of the *Electrical Review* they had heard had not diminished. But the plaintiffs claimed damages on other grounds. It was said they were entitled to damages because in the circular sent out it was said that malicious libels had been published. The articles were no doubt violent attacks upon the Medical Battery Company and all connected with the Company. The writer did not content himself with saying the appliances were not of real use, he did not content himself by saying there was exaggeration in the representations, but that there was actually fraud in the conducting of the business. It was natural the manager and those persons associated with the Medical Battery Company should say this was very strong language, and that the articles were malicious libels. The object of the defendants in sending out the circular was to remove the newsvendors from liability. He would venture to suggest that the damage, if any, caused by the issuing of the circular was of an absolutely unappreciable amount.

The Lord Chief Justice left his summing up till next morning.

On Wednesday LORD COLERIDGE summed up the case. The action, he said, was a good deal out of the common. The plaintiffs were the proprietors of the *Electrical Review*, a weekly periodical which appeared to have a large circulation. The editors appeared to be gentlemen of real knowledge of electrical science, and perfectly competent to deal with such subjects. It appeared that the Company of which Mr. Harness was a member was very much taken up with the sale of "electrical belts." The plaintiffs had denounced the "electrical belts" as impostures, and had done their best to expose what they deemed a gross system of imposture. As long as they did that honestly, and, as they believed, in the public interest, or the interest of science, they had a perfect right to do so. And the Company would have a right to vindicate their invention and to use strong language in so doing. But what they had done was to send round to 500 newsagents a circular denouncing the articles as "malicious libels." This, no doubt, was an effective, though unusual, way of preventing the circulation of the paper containing such articles. The view suggested by the counsel for the plaintiffs was that the object was to suppress the publication of criticisms upon the Company's remedies. And undoubtedly there was evidence to support that view. The jury had seen Sir E. Clarke virtually withdraw from any defence, and, of course, he would not have done so if he had felt that he had a case; but, of course, he could not "make bricks without straw." If the articles had been published with a malicious motive the Company would have a fair right to denounce them, but if they were honestly written and published it would be otherwise. The plaintiffs had a perfect right to argue that these electrical belts were quackery. The defendants must have known that such would be case for the plaintiffs. The use of the electrical belts in certain classes of cases, as hernia for instance, did seem preposterous nonsense. The plantiffs had a perfect right to say so, and to denounce a business in which sums of five or ten or 15 guineas were taken for such belts as remedies in cases in which they could not possibly be of any use, and especially were calculated to impose on persons subject to nervous disorders and who were ready to clutch at any apparent remedies. It was undoubtedly for the public interest that such pretences should be exposed and denounced. The defence set up for the publication of the circular was that notice was given to the newsagents, as necessary with a view to maintain actions against them. The jury must judge as to whether the excuse for the circular was sufficient and whether it was issued *bonâ fide*, or whether the articles had been published in the interests of truth and science and for the exposure of imposture. The latter was the case for the plaintiffs, and it had not been met by any evidence on the part of the defendants, who, on the contrary, had admitted by their counsel that their circular was libellous, and that it was a question of damages. That question was entirely for the jury. Probably there had not been much actual pecuniary damage, but the character of the paper had been aspersed, and for that the proprietors had a right to reasonable damages.

The jury, after a brief consultation, gave a verdict for the plaintiffs for £1,000. Lord Coleridge thereupon gave judgment for that amount. Counsel for the defendants asked for a stay of execution—the damages being excessive—to allow time for application to the Court of Appeal. Lord Coleridge said he saw no ground for interference.

In the Court of Appeal yesterday morning, Mr. A. G. Scott applied in the above case for leave to serve short notice of motion for to-day (Friday). It was, he said, a case in which the jury had awarded £1,000 damages for libel. The evidence was that the plaintiff's journal had increased in circulation since the libel. Within an hour of the verdict the managing clerk of the plaintiff's solicitor had called upon the defendants, demanded, and was paid £1,000.

The MASTER of the ROLLS: Then no harm can be done. You must give the ordinary notice.

CORRESPONDENCE.

BOVET MAGNETIC ADHESION APPARATUS.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: In your issue of this week M. R. V. Picou, in an article on "Bovet Magnetic Adhesion Apparatus" states:—"For large amounts of power friction must be given up and recourse had to claw clutches; but these have the great defect of not being operable during working." About three years ago I devised and patented a combined friction and claw clutch which overcomes the difficulty of engaging at any speed. Messrs. Arnold Goodwin and Son are now owners of the patent, and their enclosed circular contains an illustration which explains the construction of the clutch. It is adopted, as you can see, by electric light companies, flour mills, paper mills, &c.—Yours, &c.,

P. V. M. MAHON.

195, Clapham-road, London, S.W.,
March 8, 1893.

[The circular describes a combined clutch which is brought up to speed by friction cones, and afterwards locked by claws. The arrangement seems to be very effective.—ED. *E.*]

"THAT BLESSED WORD, 'INSTALLATION'!"

TO THE EDITOR OF THE ELECTRICIAN.

SIR: In my attempt to be brief I have apparently been obscure, and have laid myself open to Mr. Massey's very neat "score." Of course, I do not mean to substitute the general term "installation," which, like all general terms, is in itself vague, for a detailed specification and schedule, nor do I mean to limit its meaning in all cases solely to the items I mentioned. But when the items and details, whatever they may be, have been properly specified, and it is necessary to refer to them frequently by some general term in a long agreement, what is the best term to use? I should be very much obliged to Mr. Massey if he would re-write some agreements which it has been my misfortune to draft without using the unspeakable word, and without materially increasing the length of the document or impairing its clearness. If he would add to it some of the epigrammatic point of which he is so evidently a master, I should be doubly grateful. I admire his purism, and dislike the sound and length of the word in question as much as he does, but it seems to me to possess certain useful qualities. First, it is, happily, not a word is general use, and so can be limited more or less arbitrarily according to circumstances without doing violence to established usage. Secondly, it is sufficiently general to cover anything or everything, and so its vice—when used alone—becomes its virtue when used in reference to the definitely specified items which it is desired to summarise. Thirdly, it covers equally well the process and the result, and applies to the operation as well as the product, according to the context. These seem to me the reasons why I have found the word practically useful, but I am most ready to adopt a synonym or substitute if Mr. Massey will provide one. I am quite ready to be ashamed of my limited vocabulary, of which I, in common with the "authorities" of my College, have long been painfully aware.—Yours, &c. L. A. SELBY-BIGGE.

University College, Oxford, Mar. 3, 1893.

[A correspondent writing to the *North British Mail* of March 4th, on the electric lighting of Glasgow, says: "SIR,—Installation; yes, that is the word. It is a big word and sounds grandly; but what does it mean?" He then proceeds to complain that "it has not installed an extra light into Union-street."—ED. *E.*]

TRADE NOTES AND NOTICES.

[*Notices for insertion under the above heading must reach the Office not later than first post Thursday morning. New Catalogues, Price Lists, and similar matter should be sent early in the week.*]

Our readers are reminded that the 1893 Edition of "THE ELECTRICIAN" Electrical Trades' Directory and Handbook is NOW READY. This useful book contains over 1,000 pages, and several new and handy features have been added. The price of the Directory and Handbook is 7s. 6d. Postage in the United Kingdom, 9d.; abroad, 1s. 4d.

TENDERS INVITED.—*Extension of time.* - It will be seen by our advertisement columns that the time for sending in tenders for the plant and mains for the Dewsbury electrical installation has been extended to Saturday, April 8th.

——— The Manchester, Sheffield and Lincolnshire Railway Company invite tenders for various stores and materials.

——— The County Borough of Hanley invite tenders for the contracts in connection with their electricity works.

——— The Secretary of State for India invites tenders for boilers for locomotives. Tenders must be delivered at the India Office, Whitehall, S.W., by Tuesday, the 28th inst.

——— The Corporation of the Trinity House invite tenders for the supply of eleven iron mushroom anchors of 40cwt., 50cwt., and 60cwt. Tenders must be addressed to the Secretary, Trinity House, London, E.C., by Thursday, 16th inst.

TENDERS ACCEPTED.—The tender of Mr. W. Morton has been accepted by the Warrington Town Council for the erection of telephones and wires to connect the two intercepting depots at Howley and Hardy-street with the depot at Longford, the amount being £35, with an annual maintenance charge of £1.

TENDERS ACCEPTED.—The tender of Mr. James Procter has been accepted by the Burnley Town Council for the supply and fitting of patent mechanical stokers to the two boilers at the Council's electric lighting station, for the sum of £65 per boiler, less 7½ per cent. discount.

SALES BY AUCTION.—Included in a sale by Messrs. George Head and Co., at 55, Marylebone-road, London, N.W., on Wednesday next, at two o'clock, is a number of copper and other baths, some specially made electric bath coils, electrodes, batteries, indicators, &c., iron piping, insulated wires, a galvanometer, and Wheatstone Bridge coils by Latimer, Clark, Muirhead and Co. Further particulars are given in our advertisement columns, and catalogues can be obtained of the auctioneers, 7, Upper Baker-street, London, N W.

APPOINTMENT VACANT.—A working foreman engineer is required to take charge, under the Asylum's engineer, of the electric lighting installation, heating and ventilating system, laundry machinery, and cooking apparatus at the London County Asylum, Claybury, Woodford, Essex. Salary, £156 per annum, with house, coals and gas. Further particulars are given in our advertisement columns, and applications must be delivered before 9 o'clock on Monday morning, March 20th, to the London Asylums Office, 21, Whitehall-place, London, S.W.

APPOINTMENT.—Mr. W. J. Sowter, a former student of Messrs. S. Z. de Ferranti (Limited), has been appointed electrical engineer to the County Lunatic Asylum, Lancaster.

BANKRUPTCY,—Arthur Henry Wright Radcliffe, of Clare House, Claremont-road, Handsworth, Staffordshire, lately carrying on business at 10, Newton-street, Birmingham, as an electrical and telegraph engineer, has been adjudicated a bankrupt. Mr. Luke J. Sharp, of Birmingham, is the official receiver of the estate.

EDISON AND SWAN ELECTRIC LIGHT COMPANY.—This Company have recently been engaged in refitting their South Benwell Works, Newcastle, in order to compete with the heavy demand for electric light fittings, instruments, switch-boards, safety lamps, &c. The works, which will give employment to many hundreds of hands, will shortly be in full swing. New show-rooms are also being prepared over the Goldsmiths' Hall at Newcastle. These premises will be fitted up on a very elaborate scale, and an installation of over 200 lamps will be provided for. We understand that the works and show-rooms are to form a centre for supplying the Company's specialities to North of England trade buyers.

TYPEWRITERS.—Members of the electrical and engineering professions are amongst the largest users of the typewriter, and are much interested in the improvements introduced for the perfection of this useful labour-saving machine; they will, therefore, be glad to learn that the owners of the Bar-Lock Typewriter have, after several years' patient work, been successful in adding a number of material improvements to that popular machine. This is the only machine which gives perfectly visible writing, probably the most important feature of the typewriter, and one which accounts for its phenomenal success. The latest improvements include an automatic margin release key, by which margins can be regulated to any width, for the insertion of side notes, remarks, &c., without in any way interfering with the regularity of the text; six additional signs have been added; an automatic double alarm bell, by which parallel columns can be easily provided for; an automatic locking device, which prevents the key striking the paper after the full width of the line has been reached; a duplicate hard or soft roller pad for manifold copies; an automatic paper release; a backward and forward motion allowing an exact return to any spot on the paper; and a new method of forging the type bars, rendering each perfectly rigid. These, with several other smaller but still important improvements, go to make the new Bar-Lock machine the most perfect in the market. The new machine is only just completed, and readers interested in typewriters should inspect a fine specimen which has been specially made to Her Majesty's instructions for Windsor Castle, where, by the way, five Bar-Lock machines are the only typewriters in use.

MESSRS. WOODHOUSE AND RAWSON UNITED (LIMITED).—This firm send us a list of no less than thirty installations of the electric light, which they have recently completed, eight through their Dublin agency, fifteen through their Bradford branch, and seven through their London office, besides the electric apparatus for the pumping station at Crossness for the London County Council. The firm also report considerable activity in Manchester and Glasgow business.

MESSRS. JOHNSON AND PHILLIPS.—This firm send us a handsome catalogue of the specialities for which they are so well-known. The index to contents of this well-arranged book occupies three

Hosted by Google

large quarto pages. Descriptions and prices are given of a variety of dynamos of various sizes, suitable for direct current lighting, or for use with secondary batteries, all being of Mr. Kapp's design and varying from the upright horseshoe field, with the yoke in the bedplate, which Mr. Kapp claims to have introduced, to the latest alternators as supplied to the Amberley-road Station of the Metropolitan Company. The slow-speed steam dynamo exhibited at the recent Crystal Palace Exhibition is excellently illustrated, together with an example of the Central Station dynamo and "Willans-Kapp" steam dynamos. Sections are devoted to particulars of alternating current apparatus, storage batteries and accessories, measuring instruments, cables and wires, insulators, arc lamps and arc lamp accessories, incandescent lamp fittings, switches and safety devices, &c., and particulars are also given of the Brooks' patent system of underground mains. The book consists of more than 90 clearly printed quarto pages, and a considerable number of useful tables are given, wire gauges, weights and resistances of wire, decimal equivalents of feet, inches, and yards. The arc lamp sections are of course prominent, and contain a list of users of Brockie-Pell lamps, of which the makers may be justly proud. These lamps will burn for 32 hours without re-carboning. A large variety of lamps, lanterns, pillars, jibs, and other accessories are given. Compilers of catalogues must be hard pressed in these days to find something original as well as interesting to offer their customers, besides high-class printing and engraving. Two novelties which enhance the value and the appearance of Messrs. Johnson and Phillips' catalogue are scales of millimetres and inches flanking their prices of carbons, and excellent photographs of Tottenham Court-road showing the Brockie-Pell lamps.

PRINTING BY ELECTRICITY.—The *Dundee Advertiser* and the *Dundee Evening Telegraph* "are now printed by electricity"—that is, the printing offices of these journals have been equipped with the electric motor. This is the first installation of the kind in Scotland, and has proved a decided success. A 22 H.P. motor is used, supplied by Messrs. Mather and Platt (Limited), who have also supplied the necessary apparatus, and the erection has been carried out by Messrs. Lowdon Brothers.

THE ELECTRICAL TRADES' UNION.—A contest is in progress for the election of a general secretary in place of Mr. A. J. Walker, who, it appears has incurred the displeasure of some of the members of the Union. Mr. W. T. Gooday, the general treasurer of the Union, in the course of a letter on the subject, expresses a hope that all members will do their best to support Mr. Walker, who has worked very hard to make the Union a success.

INTERNATIONAL EXHIBITION AT LYONS.—A universal, international and colonial exhibition is to be held at Lyons from April 26, 1894, to November 1st following, applications for space in which should be addressed to M. de Marçay, 46, Boulevard Haussmann, Paris, by October 31, 1893. Group VIII. comprises electricity and its applications (Class 34), and general machinery and apparatus (Class 35).

NEW CABLE FACTORY IN GERMANY.—The German press states that Messrs. Basse and Selve, of Altena, Westphalia, are, in conjunction with English capitalists, about to commence the erection of large works in Duisburg, Prussia, for the manufacture of electric cables and wires on a new and improved process.

ADDLESTONE (SURREY).—A public meeting was held last week called by the Lighting Committee of the Local Board, to discuss the question of the lighting of the district. The Committee had been in negotiation with several electric lighting companies, including those at Weybridge and Woking, the latter having their wires already laid as far as Woodham Hill, from whence they could easily be extended on to Addlestone, and on to Chertsey, where the electric light was said to be in much favour. Several speakers pointed out the great advantages of the electric light, which the Woking Company were prepared to supply for £3 per lamp per annum, with a minimum of 100 lamps. It was ultimately resolved to continue on the present voluntary system for another year, and then to give the matter reconsideration. It was subsequently decided that the Lighting Committee be re-appointed, and that the lighting area be mapped out and steps taken to obtain all necessary information on the subject of introducing the electric light.

BAGSHOT PARK.—The Duke and Duchess of Connaught are having extensive alterations made at Bagshot Park, which is being sumptuously re-decorated, and the electric light is, we understand, being installed throughout.

BELFAST.—Mr. J. H. Greenhill has received instructions from the Corporation for the lighting by electricity of the chief fire station in the city at an estimated cost of £400.

BLACKPOOL.—At Tuesday's meeting of the Town Council, the minutes of the Electric Lighting Committee, fixing the charges to be made for current and showing the discounts to be allowed, were referred back for reconsideration. The Committee proposes that small consumers shall be allowed no discount, but that 25 per cent. shall be allowed on accounts of £100. It was also stated by one of the members of the Committee that after twelve months electricity will be supplied in the Blackpool district at the same rate as gas.

BURGESS HILL, SUSSEX.—The Local Board have had under discussion the question of adopting the electric light for the district, and have resolved to make inquiries as to the best steps to adopt in furtherance of this object.

CAMBERWELL.—The General Purposes Committee of the Camberwell Vestry have appointed Mr. E. Manville, of Messrs. Kincaid, Waller and Manville, to advise them "as to how best to introduce electric power into Camberwell."

CEFN, SOUTH WALES.—At the last meeting of the Rural Sanitary Authority the Parochial Committee recommended that the question of lighting by gas be deferred, and that the surveyor be instructed to obtain an estimate for the lighting of the district by electricity.

CHATHAM.—The *Chatham News* of the 25th ult. contains an account of a visit to the Chatham, Rochester and District Electric Lighting Company's central station, and an interview with the Managing Director of that Company. The account is interesting, as showing the development of electric lighting in the Chatham district of Kent.

CHISWICK.—At the last meeting of the Local Board the Clerk announced that he was about to wait upon the Board of Trade in reference to the dispute between the Board and Messrs. Bourne and Grant regarding the electric lighting of Chiswick.

COLCHESTER.—The Town Council have received an intimation that the Board of Trade are prepared to grant them a Provisional Order in the form applied for, subject to certain minor amendments. A copy of the Provisional Order has been received.

CRAIG-Y-NOS.—A supplementary electric lighting installation is being put down at Craig-y-Nos, the residence of Madame Adelina Patti, at an estimated cost of £250.

DERRY.—The tender of Mr. Matthew McClellan, builder and contractor, has been provisionally accepted for the work required in the erection of the central station for the Derry Corporation electric lighting scheme.

DUNDEE.—The Dundee Gas Commissioners have before them a large number of applications for the supply of the electric light, and altogether the Corporation's enterprise seems to be receiving public support. It was mentioned at the last meeting of the Commissioners that the consumption of gas for the past nine months exceeded by 5,000,000 cubic feet that of the previous nine months.

GLASGOW.—Sevenpence has been fixed as the charge per Board of Trade unit for electricity in Glasgow, and the charge is to be based upon the actual amount of electricity supplied.

HAMPSTEAD, LONDON, N.W.—Mr. W. H. Preece last week presented the plans and specifications for the erection of an electric lighting station in the Finchley-road, and for the lighting of the compulsory area fixed by the Provisional Order obtained by the Vestry. The plans, &c., were referred to a sub-committee for their consideration and report.

HERTFORD.—The Electric Lighting Committee have prepared a report in favour of a scheme for electric lighting, and this has been considered by the Committee of the Corporation, the majority of which are in favour of the report of the Lighting Committee, and at their meeting yesterday recommended the Council to employ an electrical engineer to advise them in the matter.

ILFORD.—A report has been received by the Local Board from the Brush Company, upon the subject of the lighting of Ilford by electricity, which, with a tender also received from the same Company, has been referred to the Lighting Committee for consideration.

JERSEY.—At the last meeting of the States the President announced that official correspondence had been sent to the Lieut.-Governor by the Postmaster-General concerning the proposed electric lighting works in Jersey, and asking that care should be taken for the due protection of the telegraphs. The States had received a petition from a manufacturing company asking for a concession. The correspondence on the subject is to be printed and circulated among the members.

Hosted by Google

KENSINGTON.—The Vestry have agreed, by a small majority, to withdraw their petition against the arrangement proposed to be entered into between the Kensington and Knightsbridge and the Chelsea Electric Lighting Companies for the transfer to the Kensington Company of a portion of the Chelsea Company's area. A discussion followed as to the advisability of the Vestry undertaking the supply of the electric light, and ultimately the matter was referred to a committee to report on the subject.

KINGSTON.—An important meeting of the Town Council was held last week, at which the minutes of the Electric Lighting Committee were presented. The minutes included a report upon the tenders received for the generating and distributing plants for the Central Station, the site for which adjoins the Sewage Works. Twenty-four firms had tendered for the whole or various portions of the work. The following tenders for the complete plant had been received :—

	Generating Plant. £ s. d.		Distributing Plant. £ s. d.
Siemens Bros. and Co. (Limited)	10,019 0 0		7,597 0 0
,, ditto	11,112 0 0		— —
Brush Electrical Engineering Co. (Ltd.)	10,247 12 0		6,896 0 0
,, ditto	—		6,236 0 0
Electric Construction Corporation (Ltd.)	8,703 0 0		9,924 0 0
,, ditto	11,718 0 0		6,561 0 0
Latimer Clark, Muirhead and Co. (Ltd.)	11,256 16 0		9,698 0 0
Sharp and Kent	12,200 0 0		6,271 0 0
New and Mayne	13,019 0 0		6,687 0 0

These tenders were investigated by Mr. W. H. Preece, who recommended the acceptance of Messrs. Siemens Bros. and Co.'s tender, which was the lowest for the station plant, and it was found that for the distributing plant Messrs. Siemens Bros. and Co. had included heavier copper mains than had been arranged for by other firms, while their schedule prices were lower. Slight modifications will reduce the total first cost to about £11,800, including the mains, this being the amount of the modified tender now recommended. Reviewing the general situation, the Committee are satisfied that their authorised capital expenditure of £16,000 will be sufficient to meet the expenses in connection with the lighting scheme, including the buildings, foundations, &c. A proposal by the ex-Mayor of Kingston that Messrs. Siemens Bros. and Co.'s tender, as modified, be accepted was, after some discussion, carried.

LECTURES.—Amongst lectures delivered during the past few days on "Electricity," we notice addresses by Mr. Alex. Siemens at Birmingham, Prof. Silvanus Thompson at the Carpenters' Hall (London), Mr. Haldane Gee at Manchester, Mr. D. O. S. Davies at Oakamoor, Prof. W. E. Robinson at Nottingham, and Mr. W. M'Whirter at the Broomloan Hall, Govan, Glasgow. In most cases the above were illustrated by experiments.

LEICESTER.—The Laing, Wharton, and Down Construction Syndicate (Limited) have written to the *Leicester Post* a letter complaining of the way in which their tender for lighting the borough has been treated by the Gas Committee of the Corporation. The letter states that, whereas the tender proposed to be accepted amounts to £27,000, exclusive of the buildings, the Syndicate's original tender for rapid-driven dynamos and vertical engines amounted to £20,310, and for slow-speed direct-coupled dynamos and horizontal engines to £23,620, or nearly £3,500 lower than the tender it is proposed to accept. The Syndicate point to the fact that the Commissioners of Sewers for the City of London awarded an important contract to them as proof of their fitness and responsibility in such matters.

NEWCASTLE.—The lighting of certain isolated sections of this city has been attended with marked success, and is continually being added to. At the last meeting of the Town Council a proposal was made that that body should take into their own hands the lighting of the whole of the city by electricity, and it was further proposed that a sub-committee be appointed to obtain the necessary information and present a report. The suggestions were carried unanimously. It is expected that a recommendation will be made to the Council at its next meeting with respect to the lighting of Gray-street, and several other propositions on the subject of electric lighting are now under consideration.

PONSONBY HALL, CALDERBRIDGE.—Mr. W. B. Turner, the owner and occupier of Ponsonby Hall, has just completed an extensive installation of the electric light, the motive power being a turbine supplied from the flow of the river Calder. We understand that several of the gentry resident in the neighbourhood have under consideration the adoption of the electric light.

RATING OF MACHINERY BILL.—In the House of Commons on Wednesday the second reading of this Bill was agreed to by a majority of 153.

READING.—At the last meeting of the Town Council the report of the Electric Lighting Committee came up for confirmation. The Committee reported that a meeting had taken place between Mr. McMullen, the electrical adviser of the Corporation, and the representatives of the Reading Electric Light Company (Limited), and it has been arranged that a clause should be inserted in the draft agreement between the parties, making provision for the working in parallel of the alternating system, and for determining beforehand the type of dynamo to be used, which clause had been duly inserted in the agreement, as proposed. The Town Clerk, in the course of the discussion which followed, stated that before the Board of Trade they had proposed an amendment that if the Corporation purchase the Company's undertaking it should not only be free from mortgages but also from any debenture or similar charges. This was a novelty and had never previously formed part of any Provisional Order, and while the Board of Trade could not admit the amendment in the form in which it had been prepared they were willing to give effect to it by altering the form of wording. The Corporation had also added to the purchase clause powers, for the Local Authority to raise money by mortgage or otherwise, in the event of their determining to purchase the undertaking. This was also a novelty and the Board of Trade did not altogether appreciate it but a suggestion which he (the Town Clerk) had made had been admitted by the Board of Trade to get over the difficulty. He was more than satisfied with the result of the interview with the Board and doubtless within a few days their decision would be received. The Committee's recommendations were approved.

ROTHERHAM.—As stated in our last issue a resolution was proposed at the last meeting of the Town Council that a Sub-Committee be appointed to inquire into and report upon the cost of electric lighting, the most suitable site, the probable revenue likely to be received, and any further information likely to assist the Council in deciding upon the question of supplying the electric light to the Borough. Mr. Hurst, who moved the resolution, submitted that the present was a favourable time for the introduction of the electric light. He gave details of the installation suitable for the Borough at an estimated cost of about £5,700, with a total possible outlay of £15,000. An addition to the resolution was moved that a canvass be made in order to enable the Council to ascertain the amount of public support likely to be accorded the scheme, with which addition the motion was carried.

RUNCORN.—A recommendation on the part of the Electric Lighting Committee of the Improvement Commissioners to have an experimental installation of the electric light at a cost not exceeding 25 guineas has been rejected, several members suggesting that further information should be provided before anything definite was attempted.

SALFORD.—At the meeting of the Town Council last week the Chairman of the Gas Committee was asked if sufficient support had been promised to the proposed electric lighting scheme to warrant the contemplated expense of £50,000, to which a reply was given that support had already been promised sufficient for an installation costing £30,000, and that further support would, no doubt, be forthcoming to warrant their incurring the maximum expenditure. In answer to a further question the Chairman of the Committee was unable to say with any certainty that the light would be ready by next winter, but efforts were being made to complete the work. In reply to another question, the Town Clerk said that no opposition was offered by the National Telephone Company to the Corporation's Lighting Bill.

SHOREDITCH.—The Parliamentary Committee of the Vestry having recommended that body to borrow £63,000 for laying down the necessary plant for their electric lighting scheme, Mr. Manville, the Vestry's electrical expert, advises them to adopt the high-tension continuous-current transformer system for private purposes, and arc lamps for the public lighting. Three sub-stations are recommended—one in the basement of the Town Hall, one at the corner of Curtain-road and Holywell-lane, and the third in Old-street. Very great economy could be effected by utilising the dust of the parish to generate the steam. Mr. Manville concludes by stating that experiments showed that the ashbin refuse of the district would prove a valuable field for the production of electricity.

SOUTHPORT.—Mr. A. J. Crompton, of the Scarisbrick Hotel, Southport, has decided upon a complete telephone, bell, and speaking tube installation at his hotel, and Messrs. Maunsell, Mercier, and Co. are carrying out the work to the plans and specifications of Mr. Walter Leake, of Victoria-buildings, Manchester.

SPENCER HOUSE.—At a dinner recently given by Lord and Lady Spencer to the Duke of York and a select party, the electric light was introduced into Spencer House for the first time. The new illuminant was unanimously voted a great success.

THE TRANSVAAL.—During last year machinery to the value of £314,200 was imported into the Transvaal.

Hosted by Google

TOXTETH PARK.—Major Cardew (on behalf of the Board of Trade) held a private inquiry last week into the dispute between the Toxteth Park Local Board and the Liverpool Electric Supply Company upon the question of the specifications and conditions upon which the Company should lay mains, &c., for supplying the Local Board's district with the electric light.

WOOLWICH.—At the last meeting of the Local Board notice was received from the Local Electric Light Company of their intention to open up the principal streets for laying mains. A central station is to be situated in Globe-lane.

WORCESTER.—Proposals made by the Watch Committee to materially modify the plans for their electric lighting scheme by the substitution of low-pressure mains for high-pressure mains in certain districts were adopted at the last meeting of the Town Council.

WREXHAM.—At the last meeting of the Town Council the report of the Lighting Committee was presented. The Committee had received a notification from the Wrexham and District Electric Supply Company (Limited) that they were now prepared to enter into negotiations for the sale of the Company's undertaking. In response to this notification an appointment was made for a meeting with the representatives of the Company at an early date. The Committee's action in this matter was approved.

WOODHOUSE AND RAWSON UNITED (LIMITED).

REPORT OF THE SHAREHOLDERS' COMMITTEE OF INVESTIGATION.

The Committee appointed by the shareholders at the annual general meeting held on the December 22nd last to enquire into the affairs of the Company, convened a meeting at the Cannon Street Hotel on Tuesday for the purpose of presenting the report of its investigations. Mr. W. S. Squire presided, and there was a large attendance.

The CHAIRMAN read the report of the Committee, which was as follows:—

"The Company was formed in 1889 by the purchase of several companies from Woodhouse and Rawson (Limited), who were the vendors, for £269,000. The vendors stated in the original prospectus that they had been carrying on business very profitably, and, as an inducement for the public to subscribe, they undertook to guarantee the new Company a dividend of 15 per cent. on the ordinary shares for three years, and to deposit £75,000 with them as a guarantee. The way in which this was done was simply to leave £75,000 of the purchase money unpaid. This, no doubt, was legitimate. At the end of the first financial year (1890) the Directors presented their first annual report, showing a gross profit of £99,399. 7s. 8d., reduced by certain charges to a net profit of £61,085. 1s. 9d. Out of this, dividends of 15 per cent. were paid on the ordinary shares and 8 per cent. on the preference shares, £25,000 was carried to reserve, and £16,335. 15s. 3d. was carried forward. There was no explanation of how these profits were arrived at, or any statement of the amount of commission paid to the Managing Director. Your committee have to report that a considerable portion of these profits consisted of very doubtful items, which, in their opinion, should not have been carried to profit and loss at all, and were certainly not legitimate trading profits. The first of these items was £25,000, an amount received from the Kensington Stores for leasing to them the front portion of the Cadby Hall property. This item the auditors of the Company at first refused to pass, and only consented to do so when informed that the Directors had taken counsel's opinion. The second item relates to Jensen's Bell. This property was purchased in September, 1889, for £2,050. It was straightway entered in the books at £3,920, and the difference between the two amounts—viz., £1,870—was considered as profit. The Directors also took credit as a business profit for £4,050 premiums received on their issue of shares. The fourth item was £37,240, being the balance for promoting the International Okonite Company. This was entered in the books on the last day of the financial year—viz., June 30, 1890—but the prospectus was only issued on the first day of the next financial year, and it must have been some considerable time before it could be seen whether it would be successful, or whether there would have been any profit at all. Not one penny of this profit accrued in cash; it was all in bonds and shares. The result was that at the end of the next financial year, to which the operations really belonged—viz., July 31, 1891—Woodhouse and Rawson were left with 1,462 ordinary shares, valued at £8 each; 539 preference shares, valued at £9. 15s. each; 255 debentures of £100 each—of a total somewhat depreciated value of £42,951. These securities were in the following year (1892) valued at £4, £6. 10s., and £100 each respectively, having originally cost par price. They are still in the hands of the Company, and are to a large extent unsaleable. Your committee are of opinion that these securities should have been carried to a suspense account, and not considered as divisible profit until realised; and, further, that the profit, such as it was, properly belonged to the second year's trading. These four items come to £68,160. Assuming that the Directors were technically justified in carrying the £25,000 for the Kensington lease and the share premiums to profit and loss, there remains a sum of £39,110, which, if rejected as not being legitimate profits, would reduce the net profit from £61,085 to £21,975, in which case the Managing Director would not have been entitled to commission. One result of the profits of the first year being swelled in this way was to entitle the Managing Director to a large commission. Most of the shareholders are probably unaware that at the formation of the Company a contract was made with the Managing Director which provided that if in any one year the profits were more than sufficient to pay 15 per cent. on the ordinary shares, he was to receive 25 per cent. of the excess as commission. He did, as a matter of fact, receive in respect of this year's trading a commission of £13,775, of which more than £10,000 was in cash. Secondly, he was the liquidator of Woodhouse and Rawson (Limited), the vendor company, in which he was largely interested. It would benefit those interested in that Company to get the guarantee fund of £75,000 (which had served its purpose in attracting the public) out of jeopardy as soon as possible. Accordingly, two months after the issue of this balance-sheet the shareholders were asked by the Directors to consent to the repayment, as the Directors 'had a confident assurance that the rate of dividend would be maintained.' Your committee have a confident assurance that if the shareholders had been told, or been allowed to know, in what way the profits of the first year had been arrived at, no sane shareholder would have consented to part with his guarantee. For, whatever opinion may be entertained of the technical right of the Directors to carry the £25,000 for Kensington and the premium on shares to profit and loss, these items can be, at best, looked upon as windfalls peculiar to that year, and impossible of repetition. They could not, therefore, justify the confident assurance they expressed that this rate of profit would be maintained. The £75,000, while it remained a guarantee fund bore no interest. By the way in which it was repaid it was made to come before both the ordinary and preference shares; it at once began to bear 5½ per cent. interest, and has nearly doubled the debenture debt of the Company. It is just the large amount of this debenture debt which makes it so difficult to reconstruct and save the Company. The terms of repayment were a rebate of £12,000, £12,000 in cash, and £51,000 in debenture stock. Your committee now turn to the year ended July 31, 1891. The £12,000 rebate on the £75,000 was placed to credit of profit and loss; so that a transaction which was really a source of heavy loss, and has done more than anything else to ruin the Company and prevent its reconstruction, was actually claimed to have resulted in a net profit of £12,000. The next item of profit is £14,975 appreciation of founders' shares in the Phœnix Trust Company. Twenty-five founders' shares in this Company are stated to have been purchased for £25, and were then entered in the books of Woodhouse and Rawson United (Limited), as being worth £15,000, the difference, viz., £14,975, being considered as profit. The Phœnix Trust Company appears to have been practically a *nom de guerre* of the well-known Baron Grant. The books show numerous transactions in which the Phœnix Trust Company have been jointly interested with Woodhouse and Rawson, Limited, and, in one case, at least, the Phœnix Company took three-fourths of the profits. The paid-up capital of the Phœnix Trust Company being almost nominal, it was able to pay on its shares held by Woodhouse and Rawson United, Limited, a large dividend which consisted almost entirely of paper. The Directors of Woodhouse and Rawson United, Limited, then capitalised this dividend, and called their 25 shares worth £15,000. Woodhouse and Rawson United, Limited, being in difficulties, the Phœnix Trust Company has gone into liquidation, and its shares are worthless. Woodhouse and Rawson United, Limited, having acquired the control of the Epstein patents for accumulators, formed a company called the Epstein Accumulator Company, with a nominal capital of £100,000. Of this, shares worth nominally £70,000 were allotted: 55 per cent. (£38,500) to Woodhouse and Rawson United, Limited, and 45 per cent. (£31,600) to Mr. Epstein. Woodhouse and Rawson and Epstein both gave 10 per cent. of their shares—say, £7,000 altogether—to the Phœnix Trust Company. The whole of this transaction was absolutely on paper, not one penny of capital being subscribed; yet after deducting the 10 per cent. to the Phœnix Trust Company, and certain expenses, Woodhouse and Rawson United, Limited, take credit for £31,630 net profit, which is brought into the profit and loss account as divisible profits. The Epstein Accumulator Company's shares may be worth much or nothing; it is a thing to be tested in future by actual practice. Your committee may here refer to the relations between the Epstein Company and Woodhouse and Rawson. By an agreement dated July 31 (again the last day of the financial year) the expenditure and liabilities of the Epstein Company up to that date—amounting to £3,780 12s 6d., together with a further agreed advance of £7,500—were to be borne by Woodhouse and Rawson United, Limited. This sum—amounting to £11,280 12s. 6d.—was to be repaid to Woodhouse and Rawson United, Limited, only in the event of shares to double this amount being issued and paid for by the public; so that, in the event of no such issue being successful, the advance will not be repayable. Yet the whole of this advance is put down as a good asset, and the shares taken as profit as well. Another item of profit is £15,188, being the profit on the Issue of French and Austrian Elmore Companies; but these are all in paper, and practically unsaleable. Other items are £1,000 shares held against the Phœnix Trust Company, and 1,000 £1 shares of the National Financial Company, which appears to be mixed up with the Phœnix Trust Company. These the Directors have put down as being worth £2,000, the difference being called profit. Then again, the value of the Kidsgrove works is again raised to the extent of £2,640, though these works, in one way or another have been a source of loss to the extent of £40,000 or £45,000, and the Kensington works are appreciated £1,000. These various items, added together, come to £81,233, while the net profits claimed for the year amount (including these items) to no more than £51,439 4s. 5d. Your committee are of opinion that in these two years the profits have been apparent rather than real, and that the dividends ought to have been paid out of the guarantee fund. In the third year the inevitable Nemesis began to overtake the Company. The losses at Kidsgrove and elsewhere, and the disastrous effects of the attempts to infringe other persons' patents, had to be confessed. The unsaleable

Hosted by Google

securities had to be written down, and the opportunities for showing apparent profits were exhausted. The result was a heavy loss. Great as the loss appears to be, it is understated. To take one instance. The Directors met the shareholders on December 22nd last with accounts in which the 25 founders' shares of the Phœnix Trust Company still figured for £9,156. On the following day this Company went into voluntary liquidation. That this would be so must have been known to your Managing Director when he faced the shareholders, as he held one-fourth interest in that Company. The total paid-up capital of the Phœnix Trust Company was £1,124 up to December, 1892, and it is remarkable that in the list of shareholders at Somerset House the name of Woodhouse and Rawson United (Limited) does not anywhere occur. Your committee think it their duty to report to the shareholders that in the very month in which the Directors induced the shareholders to assent to the repayment of the £75,000 they were borrowing money at 10 and 12 per cent. to pay the dividends, and at this very time the account of the Managing Director with the Company was overdrawn more than £20,000, In another instance, the interest works out at 22 per cent. On January 15th £9,500 was borrowed from Mr. Wood at 10 per cent. interest; if not repaid by April 15th a fine of £500 was to be paid. It was not repaid, so that this for the three months amounts to an interest at the rate of 30 per cent. per annum. At this time the Managing Director's debt to the Company was £20,833, for which he was charged 6 per cent. per annum. Your Committee find that on December 12 last, a few days before the general meeting, the Directors agreed by deed, under the seal of the Company, to cancel the debt of the Managing Director on his giving £18,480, the balance then due, in Second Debenture Stock. The deed is attested by Sir Rawson Rawson (the father of the Managing Director) and Mr. S. Pope, Q.C. These debentures were to be accepted at par price, though their market value was not half that, and not saleable at this price. The amount was due in cash, and not in depreciated paper. The Company was put forth to the public as an electrical manufacturing company. Your Committee find that the manufacturing department has been utterly neglected and shamefully mismanaged, while the Managing Director has devoted his energy to hunting financial will-o'-the-wisps. As a consequence, the manufacturing carried on by the Company has not been profitable, and, probably from the same cause, none of the branches or agencies of the Company have shown any profit. Your committee have visited the Manchester, the Kidsgrove, and the Kensington works. The Kidsgrove purchase they regard as particularly unfortunate. The purchase was decided on hastily, without proper professional advice, and the price paid was enormously in excess of its value. The plant is for the most part antiquated, the situation unsuitable; the assets taken over turned out bad, and the contracts then on hand have resulted in a heavy loss. Your Committee have endeavoured to arrive at the present financial position of the Company, computed on a rational basis. In order to do this, they insisted on the stocks as at December 31st being properly taken, and they would have been in an position to have reported earlier to the shareholders if greater diligence had been exercised in taking these stocks. As the stocks evidently contain a good deal of antiquated apparatus, they have taken this at two-thirds of its nominal value. The securities, which stood at July 31 last at the nominal value of £101,827.5s., being for the most part unsaleable, as matters stand at present, they have cut these down to £25,000. The goodwill was at that time put down as worth £99,263. 3s. 7d., and the patents at £73,450. 18s. 1d. The Managing Director and other persons interested have failed to convince your Committee that their real intrinsic value is anything like this amount. The goodwill of a business losing money is, obviously, worth very little. They have, therefore, taken patents and goodwill together at £20,000. They have endeavoured to value the assets and ascertain the liabilities, and have come to the conclusion that the Company is just solvent; that is to say, that under an intelligent realisation, there would be just enough to pay off the liabilities, including the debentures and debenture stock. With regard to any proposal for carrying on the Company, the main difficulty consists in the heavy debenture interest, £9,350, to which must now be added £2,000 interest on the secured debenture stock, authorised at the last general meeting. This is an intolerable weight for the Company, with its diminished resources, to bear. Your Committee visited the Cornbrook and Kidsgrove works, and were favourably impressed by the managers there. Neither were sanguine. The former thought that if £500 were spent in new plant, he might be able to make £1,000 or £2,000 a year; the latter thought that if £7,000 additional capital were given to him, he might be able to make a profit of about £2,500 a year. Mr. Stutchbury, at Cannon-street, thought that the merchants' business might possibly produce £4,000 a year. In what is called the financial business the only chance seems to lie in the Epstein business, which Mr. Epstein estimates might produce £5,000 a year, one-half of which would come to this Company, and there is also a rent of £500 paid by his Company. All the profit thus visible to your Committee is £11,000 a year. Unless the vendor company can be made, or is willing, to revert to the original arrangement, this profit would be only just sufficient to meet the debenture interest, and there would be no inducement for the shareholders to subscribe fresh capital. It seems clear that it is no use attempting to raise capital which would be subject to the existing debentures. A more hopeful proposal would be that a new and perfectly independent company, under fresh management, should be formed, which should lease from the old Company their existing works and plant; that this Company should carry on the existing manufacturing and merchant business, which is of considerable volume, buying from and selling at a commission for the old Company the existing stock; and, as the assets are realised, the debentures might be paid off. A company with a small and reasonable capital, unburdened by a heavy debenture interest, might be able, under these circumstances, to make a living profit. It is only within the last few days that your Committee have been able to ascertain the position of the Company, and they are not prepared to propose any more definite scheme for the future. This requires more mature consideration than they have been able to give to the subject in the short time at their disposal. Your Committee would draw attention to the extremely small holdings of some of your Directors, who have had, consequently, a very small stake in the prosperity of the concern. The Chairman (Sir W. R. Rawson) holds 70 shares; Sir John Stokes, 51 shares; Sir Edward Thornton, 50 shares; Mr. Samuel Pope, Q.C., 222 shares; Mr. Philip Rawson, 374 shares. Your Committee cannot close this report without saying that the accounts and everything connected with the Company are in the greatest confusion, and they are indebted to the able assistance of the auditor of the Company (Mr. Pixley) and Mr. Thomas Pilling, of Manchester, one of the Committee."

Mr. PILLING, of Manchester, an accountant who had been engaged by the Committee to examine the books of the Company, submitted a communication which, if anything, was even more condemnatory of the management than the report of the Committee.

The CHAIRMAN then went on to say that the foregoing statement represented what was practically the position of the Company. He did not think that it need have made any losses at all. It was quite impossible —and the public could not realise this too soon—for £15,000, or £20,000 working capital to earn a dividend on £100,000 nominal. But if this Company could in some way be freed from its enormous liabilities, and particularly its debenture stock, there was in his opinion—and he believed that in stating it he was giving utterance to the belief of most members of the Committee—no reason why this should not be made a fair working property in proportion to its resources. If they desired to carry on the Company it could only be done by a scheme of reconstruction, which put any new money subscribed in a position of safety, and not liable to be swallowed up by the debenture holders. Subject to that he thought that the industrial part of the business might be carried on at a moderate profit; but it would require a great deal of consideration before anything like a definite scheme could be propounded. He concluded by stating that the Committee were much indebted to Messrs. Pilling and Bacon for the trouble these gentlemen had taken in investigating the affairs of the Company.

After a few remarks from General FYFE, more or less of a personal nature, and from Mr. SWAIN,

Mr. F. L. RAWSON (the Managing Director) made a statement in vindication of his own action and that of the Directors. He admitted that they had made the mistake that all the Directors of other companies had made, namely, that of putting down the assets at too high a figure. What they did was to go on the market quotations, and possibly they had made errors in the valuation. They had tried to enlarge the industrial business, and they thought that they had efficient management, but found too late that that was not the case. His whole time in connection with the Company had been thoroughly devoted to the interests of the shareholders, and those friends whom he had brought into the concern for whom he held himself morally responsible. He had never had a penny out of the concern in any way.

Mr. SAMUEL POPE, Q.C., also addressed the meeting at some length. He said that he did not feel surprised that there should be anger among the shareholders. He himself felt angry because, whatever happened, he must be a very considerable loser. He had done everything he could to avert disaster. He had found thousands of pounds, and had become liable for thousands more to keep the Company on its legs that they might go there to discuss what was the best thing to be done in the interests of all parties. He occupied the position of being not only a director, responsible, no doubt, for the acts of the Directors morally, it might be even legally, but, unfortunately, he held the position of being a trustee for the 5½ per cent. debenture stock, so that he stood in two relations, while he had to do the best for the shareholders to see that the assets should not be squandered to their detriment. He did not feel that he ought to desert the ship because it had got into shallow water. He wished that he could run away and hide his head from that report. He believed that most of the facts stated in it were true. He did not quite agree with all the deductions that the Committee drew. What he wished to impress on the shareholders was this, that they must not blame the Directors for not being wise before their time. He ventured to say that not one of the shareholders would dare to rise and say that he believed that any Director was a party to a fraudulent valuation. The report said that they were founded as an industrial Company. This was so, but an important part of their business was to assist in the introduction through public companies of electrical inventions. He remembered well when he became a Director of the Company that Lord Aberdare said that they looked upon their industrial business as their backbone. He wished that they had kept it as their backbone. Instead of looking after the industrial part of the business, the Manager was looking after financial schemes from which large profits had been previously made. It seemed to him, however, that nothing could be worse in the interests of all parties than a hostile winding up, and he would tell them why. It would mean the realisation of the assets—if they liked of questionable assets—but it would mean the realisation of the assets under the worst possible conditions. It would be a sacrifice, contrary to the interests of anybody, of any possible value that these assets might have. Therefore, however they might blame the Directors, they must stand or fall by what they had done; but at least let them be reasonable, and face the position. Everyone ought to put his shoulder to the wheel as far as possible to prevent the disaster of a hostile winding up. This must be done, or the the whole concern would go to the wall. The only way he could suggest was to call an adjourned meeting of the shareholders and discuss some scheme of reconstruction which would commend itself to the general body of shareholders and debenture holders.

The CHAIRMAN said that this was not, properly speaking, a meeting of the Company at all. The proper course was to call an adjourned meeting and follow the course suggested by Mr. Pope. He did not doubt that their Manager's efforts to make a profit for the Company had been honest, but he had made the mistake of going into financial affairs right and left.

Hosted by Google

Mr. ABRAHAM paid a warm tribute to the conduct of Mr. Pope in all his relations with the Company, and reminded them that this was not a meeting at which any decided action could be resolved upon. They must wait till the adjourned meeting, when the Board would have been put in possession of the Committee's report, and would be able to state their case in reply.

After some remarks, from Mr. GRIFFITHS, mainly on the lines of the report of the Committee,

The CHAIRMAN, in reply to Mr. Bond, said that the Committee having discharged the duties for which it was appointed ceased to take any further action as such.

Mr. BACON proposed, and Mr. PEAT seconded, a resolution to the effect that the report of the Committee and the subsequent discussion should be printed and circulated among the shareholders. The former said that the report would have been stronger than it was in some parts, but out of deference to some of their members certain excisions had been made.

Mr. F. L. RAWSON added that the Directors had been taking the advice of some practical business men upon the question of reconstruction, and a large debenture-holder had made a suggestion, in which he was bound to say neither the Committee nor the Directors had found any flaw. If adopted, this would protect the interests of the debenture and debenture-stockholders, and would, at the same time, save some of the shareholders' money, and enable those now interested in it to get a return in the future. The Directors saw no reason why that scheme should not be laid before the shareholders at an early date—certainly before the end of the month. (Hear, hear.)

Mr. MADDISON said he represented some debenture and debenture-stock holders, who felt that every opportunity should be given to the shareholders to save the assets of the Company as a going concern (hear, hear).

Mr. POPE remarked that a special general meeting could be convened by the Directors to follow the adjourned annual general meeting, and a scheme of reconstruction could then be considered.

The proceedings terminated with a vote of thanks to the Chairman.

COMPANIES' MEETINGS & REPORTS.

Consolidated Telephone Construction and Maintenance Company (Limited).

An extraordinary general meeting of this Company was held yesterday at Winchester House, Old Broad-street, Mr. C. L. W. Fitzgerald presiding,

The SECRETARY (Mr. Charles Curtoys) having read the notice convening the meeting,

The CHAIRMAN said: Gentlemen, the resolution I have to propose, condensed, means that your Directors suggest to the shareholders that the £1 Preference shares be paid off at par, that 2s. be returned on the Ordinary shares, and that the share of 14s. nominal value be written down a further 2s., making each share 10s. nominal value. I must, to make matters clear to you, go back somewhat into the past history of the Company. In the year 1881 your Company bought certain concessions in Austria, and then formed a subsidiary Company, called the Telephone Company of Austria, to work those concessions. Unfortunately, the Directors of that period were unable to obtain capital for this Austrian Company, and the whole burden of providing money fell on the Consolidated Telephone Company. This proved such a drain that it very nearly ruined your Company. When myself and colleagues in 1884 took the management of your affairs things had come to the pass of certain persons agitating for the cancelling of the concessions, on the ground that the business was not being worked properly. We found a book debt owing by the Telephone Company of Austria to your Company of many thousands, and eventually we received £34,500 Austrian Debentures for that book debt. Some £15,500 has been also advanced by your Company against Austrian Preference Shares, and we hold £28,355 Austrian Ordinary Shares—the shares received for the concessions. The concessions purchased were for the short period of only 10 years, of which three had elapsed. The subscription to the Telephone Exchanges were only at the low rate of £6 per subscriber. When we examined the concessions in 1884 I think we should have decided not to go on with the installation, although we had already at stake the sum of £34,500, because the clause relating to the termination of the concession was somewhat obscure—but for the fact that the then Minister of Commerce in Austria had written a letter to the effect that in the event of the Austrian Government purchasing our telephone business it was to be bought at the commercial value—that is, on the basis of net profits also. It was verbally stated that if the Company's installation were not so purchased we should have a prolonged concession. We were satisfied, and worked the business energetically, doing everything that was asked us, and fully satisfying the Austrian public as well as the Government. Time went on, and at last we approached the Austrian Government with a view to finding out their ideas as to purchasing or renewing the concession. The Government decided on purchase, but to our astonishment entirely repudiated the letter of the Minister of Commerce, and said their view was to purchase us at cost of material. Anything more unfair cannot be conceived; we had made a splendid business, and were simply to get no profit. To show how much the Austrian Government benefited, I will mention that, during the concessions, the Company paid as interest on its debentures and shares some £20,000, while the Austrian Government, in taxes and royalties, received no less than £13,000 in the same period. Myself and two colleagues went twice to Vienna to plead your cause, but, in spite of our getting the assistance of our Ambassador, and very powerful assistance from influential personages in Austria, we could not move the Government from their point, and at last, only one day before the end of the concession, we had to take the terms offered. The bulk of the purchase money having been paid and sent over here has led to our calling you together to-day. We have received the £34,500, and most of the £15,500 Preference, which will enable us to pay off our 6 per cent. Preference shares and return 2s. on the Ordinary shares. Owing, however, to the Austrian Government not having fulfilled their bargain, which bargain if carried out would have made valuable the £28,355 Austrian Ordinary which you hold, we are under the necessity of asking you to write down the nominal value of your shares by a further 2s., making them 10s. instead of 14s. If the resolution I have now to move is carried to-day, we shall take the earliest steps to obtain the sanction of the Court and return the money to the shareholders without delay. He concluded by moving:—

"*That the capital of the Company be reduced from £307,545, divided into 75,000 Preference shares of £1 each, 75,150 Ordinary shares of £1 each, and 224,850 Ordinary shares of 14s. each, to £234,988, divided into 47,362 Preference shares of £1 each, and 75,150 Ordinary shares of £1 each, and 224,850 Ordinary shares of 10s. each; and that such reduction be effected by returning the amount of £1 per share credited as paid upon each of the 27,637 issued Preference shares of the Company to the holders thereof, and thereupon cancelling such shares, and by returning 2s. per share to each of the holders of the 224,850 issued Ordinary shares of the Company, and by writing off each of the said 224,850 Ordinary shares the sum of 2s. per share as being capital unrepresented by available assets.*"

Sir ALEXANDER ARMSTRONG seconded the motion.

A shareholder asked whether, if they realised the 28,355 Austrian Ordinary shares, it was necessary to write down the 2s. a share.

The CHAIRMAN said that it was impossible to say how much they would pay back until the Austrian Company was liquidated.

The motion was then carried, and the proceedings terminated.

House to House Electric Light Supply Company (Limited).

We learn that the fifth ordinary general meeting of this Company was held at the Central Station, Richmond-road, S.W., on Thursday, last week under the presidency of Mr. H. R. Beeton. We were not, for some reason, favoured with a copy of the Directors' report, and are indebted to an outside source for the following account of the proceedings at the meeting:—

The SECRETARY read the notice convening the meeting, and the report of the Directors and statement of accounts were taken as read.

The CHAIRMAN, in the course of his remarks, stated that the whole of the capital expended had been laid out with the strictest economy, and by the Company's own staff without having occasion to have recourse to the more or less costly services of consulting professional engineers. This expenditure amounted to £11,391. 12s. 3d, and represented the construction of a large portion of the second smoke stack, which would suffice for the completed station, giving three times the power at present possessed, and an addition to the plant equal to the supply of 28,000 35-watt lamps, so that the capital expenditure was larger than was necessarily represented by the revenue which appeared on the face of the accounts. With regard to revenue, for the first time in the history of the Company continuous day and night running had been undertaken. In these circumstances it was matter for congratulation that with the heavy extra consumption of coal and labour which they had to face, the cost of working should amount to no more than that for 1891. For this reason, and for others revealed by a more detailed analysis of the accounts, he thought he could promise the shareholders, by a limited capital expenditure on the sub-stations for securing more economical distribution, more satisfactory results in the future. They would agree with him that the Debenture and Preference shares constituted as good an investment as the market for this class of property afforded, and it was matter of regret to him that the hopes of the ordinary shareholders remained still to be fulfilled. The fact was that in this, as in other similar enterprises, they had drawbacks to contend with, but, unfortunately, their drawbacks were in the present, and their compensations in the future. The situation of their central station was such that it could never create a nuisance to the neighbourhood, and secured them from all possibility of difficulty and disturbance with the growth of their business in the future, but it imposed upon them a system of distribution which probably—he said probably, only—involved a more expensive method of distribution in earlier stages of their business. Moreover, laying mains as they had done in all the thoroughfares scheduled in the area, had resulted in only a sparse distribution of lights, as the statistics of other companies showed, so that there remained nothing for them but to wait patiently for the success which he believed would ultimately result. He then moved the adoption of the report and accounts.

The MANAGING DIRECTOR seconded the motion, and stated that they had made certain alterations in the arrangements of their steam pipes. Their old system was found to be very wasteful. These improvements were completed towards the end of last year, and the accounts for the ensuing year ought to show a great saving of coal, &c. Another point he wished to mention was the laying down of sub-stations, as under the old plan of putting in a converter in every house for reducing the electricity from high to low tension a great loss of current was apparent when the demand became extended. To avoid this the Directors had decided to adopt the system of grouping the converters in convenient places by which any portion of the mains could readily be got at and switched off when not in actual use. This, when completed, should show a marked improvement in their revenue.

Hosted by Google

Mr. ARTHUR KIMBER asked what was the number of lights which had been connected since January 1st.

Mr. FROST asked if the Directors could not pay an interim dividend, as most companies were accustomed to do.

The CHAIRMAN replied that the number of lights connected since the 1st of January this year was about 1,500, and that the subject of paying half-yearly dividends upon the Preference shares would receive consideration.

The report was then adopted.

The dividend on the Seven per Cent. Preference shares was declared; Messrs. William Page and R. A. Germaine were re-elected to their seats on the Board. Messrs. Theobald Bros. and Miall were re-elected auditors, and the usual vote of thanks terminated the proceedings.

The following is the report of the Directors:—

The revenue account for the year ended December 31st, 1892, shows a credit balance of £2,836. 19s., which, with the sum of £525 referred to below, and the balance of £291. 0s. 8d. brought forward from the previous year, makes a total of £3,652. 19s. 8d. The Directors propose to deal with this amount as follows:—Interest paid on £30,000 debentures, £1,800; in reduction of preliminary expenses, £500; in reduction of suspense renewals account, £100; depreciation fund, £250; dividend of 7 per cent. on amounts paid up on £21,155 Preference shares, £962. 5s. 5d.; leaving a balance to be carried forward of £40. 14s. 3d.

The Directors have the pleasure to report that during the past year the business of the Company has continued to increase; the number of lamps attached to the Company's circuits on the 1st January being the equivalent of 19,383 8c.p. lamps, and on the 31st December 23,700. At the beginning of the year there were 373 houses connected, and at the end of the year 471. During the year another unit of plant has been laid down. This addition admits of the number of connected lamps being increased to 23,000 8-c.p.

A further issue of Seven per Cent. Preference shares was made during the autumn, bringing the total preference capital issued up to £21,155.

In addition to the profits at Kensington, the sum of £525 is guaranteed to the Company for the year 1892 in connection with the business of Central Station Construction, which the Leeds and London Electrical Engineering Company, Limited, took over from the Company, a similar amount being guaranteed for the current year.

The Directors have drawn no fees during the year, but £200 has been paid to Mr. William Page for special services.

Cambridge Electric Supply Company (Limited).

The annual general meeting of this Company was held at the offices, Sidney-street, Cambridge, on Friday, under the presidency of the Rev. G. B. Finch.

The Directors' report, which was taken as read, contained the following:—

"The Deed of Transfer of the Cambridge Electric Lighting Order, 1890, by the Corporation to the Company, was completed on December 13, 1892. The number of shares issued up to the present time is 1,836. A site in Thompson's-lane was adopted for the generating station, and the works were commenced at the end of July, 1892. The supply of electric energy to consumers was begun on November 19, 1892, at which time the number of lamps in electric connection with the station was equivalent to 230 10 c.-p. lamps. The number of lamps connected at the present time is equivalent to 4,700, and the number actually applied for to 6,200 similar lamps. Two steam boilers, one steam superheater, one economiser, and three turbine-alternator dynamos, each capable of supplying current for 3,500 10-c.p. lamps at the same time, and all other requisites for a complete central station have been set up. A length of five miles of double cable has been laid down in iron pipes in the streets, and seven colleges have the mains in their courts and are consumers of the current. The engine-room, boiler-house, and chimney shaft at the station have been built in a good substantial manner. The engine-room and shaft are large enough for the supply of 30,000 lamps. A strong river wall, consisting of iron piles, 30ft. long and 4ft. apart, with timbering between, is in course of construction, and will be completed in a few days. The Directors deemed it expedient that the Company should themselves undertake the wiring of houses and buildings and the supply of fittings—at all events, for a time—and a considerable amount of this work has been executed by the Company. The prices charged have been made as low as possible, consistent with securing a moderate profit, which has been realised. The total expenditure incurred up to the present time amounts to about £22,000, and a considerable further expenditure will be required for some time to come. The demand for current from the outset of the Company's operations has been much greater than the Directors anticipated, and a considerable extension of the Company's mains and works is, and will be, necessary to fulfil the present and future requirements of consumers. The Directors propose for these reasons to make a further issue of £10 shares, on which it is intended to call up not more than £8 per share. The amounts paid for these shares will rank for dividend on an equal footing with the other shares of the Company, but from the respective time only when the several amounts are paid, and in proportion to such amounts. The Directors are gratified with the success which the enterprise has met with in Cambridge, and they regard the position of the Company as most satisfactory and encouraging."

The CHAIRMAN, in moving the adoption of the report, said that of course they had not much progress to report in regard to the conduct of the business as a profit-earning concern. Their main business had been in regard to the construction of the works, and he was very glad to be able to report that the works were substantially completed. They were making provision for more lamps than would have been provided under the extension scheme contemplated by the Corporation, and, whereas the Corporation were providing for an outlay of £40,000, the Company's outlay, including the land of the Abbey estate, which they were not using, and the £1,000 they paid to the Corporation, was £25,000. That was due to two causes. One was the greater simplicity of the machinery under Mr. Parsons' system, by which a very great saving was effected in the size of the building and cost of machinery, and the other was they had not let the work out to contract, but had been doing it themselves. He explained that the Directors had no anxiety whatever in the matter of capital, and said that they might look forward to paying before long a reasonable dividend.

Sir B. C. BROWNE seconded, and stated that the Company had been formed on lines similar to that of the Company which was successfully carried on at Newcastle, and which was now paying 5½ per cent. interest. His impression was that the Company was working well and satisfactorily.

The motion was unanimously agreed to.

Sir B. C. Browne and Mr. Munsey were re elected Directors, and Mr. Arthur Rutter was appointed auditor.

The question of the remuneration of the Directors was postponed until the next meeting, and the meeting concluded with a vote of thanks to the Chairman.

Northampton Electric Light and Power Company (Limited).

The annual meeting of the shareholders of this Company was held recently in the Old Council Chamber, Town Hall, Mr. R. Cleaver, J.P., occupying the chair.

The fourth annual report stated that the business of the Company continued to increase, and that the electric light is steadily making its way. At the present time there are more than 4,000 8-c.p. lamps, or their equivalents, connected with the Company's mains, and not a few of the original customers have shown their appreciation of the light by extending its use. The debentures referred to in the last report, amounting to £5,000, have all been taken up, and the interest upon them has been punctually paid. After providing for debenture interest there is a balance of profit, £87. 15s. 1d., which will go in reduction of the deficiency necessarily occasioned last year by working expenses having been incurred for some months before the accession of customers. The third engine-set will be shortly in working order, and will be an invaluable addition to the Company's resources. To meet the additional cost it was resolved to issue Six per Cent. Cumulative Preference Shares to the extent of £5,000, and these have been allotted to the amount of £3,180. The Directors have secured, after protracted negotiations, some property adjoining the Company's works in Angel-lane, for the erection of coal sheds, which will result in a substantial saving in the way of cartage and there will be abundant room for any future extension of the works. The chief engineer, Mr. B. R. Beale, has given up his position, but most kindly continues to devote a considerable amount of time and energy to the promotion of the Company's interests. He is succeeded by the second engineer, Mr. W. E. Heenan. The statement of accounts showed that the sale of current for the year realised £1,182. 19s. 5d., and that, as stated previously, there is a profit of £87. 15s. 1d. on the year's working.

The adoption of the report and accounts was moved by the CHAIRMAN and carried unanimously, great satisfaction being expressed at the position and prospects of the Company.

The retiring Directors, Messrs. Seekham and Manfield, having been re-elected, votes of thanks to the Chairman and the auditor closed the proceedings.

South Staffordshire Tramways Company.

The annual meeting of this Company took place at the Depôt, Darlaston, on Wednesday in last week, Mr. W. J. Carruthers Wain being in the chair.

The SECRETARY read the notice convening the meeting, and also a circular which had been issued by the Chairman to the shareholders, stating that he intended to move the adjournment of the meeting, as a libellous circular, full of misleading statements, had been secretly and at the last moment issued to certain selected shareholders, but not to the Directors or officers of the Company.

A short and stormy discussion was held, and the meeting resolved by an overwhelming majority to adjourn.

The following is the report of the Directors to be submitted to the adjourned annual meeting:—

"The receipts for the year ended December 31, 1892, have increased by £656. 13s. 7d. over those for the twelve months to December 31, 1891, and were 13·47d. per mile run, as compared with 14·03d. for the previous year, and the average fare per passenger carried was 1·50d., in comparison with 1·52d. for 1891. The total expenditure has decreased by £311. 8s. 11d., and is at the rate of 11·90d. per mile run, as compared with 12·86d. in the previous year. The profit on the working amounts to £3,172. 19s. 8d., to which must be added the amount of £1,064. 12s. 9d. brought forward from last year, less the amount of £600 placed to reserve and renewal account, and after providing £1,781. 11s. 8d., the amount due for interest on Debenture Bonds, and £57. 12s. 8d. for income tax, a balance remains of £1,798. 8s., of which, following the auditors' recommendation, it is proposed to carry £1,200 to the reserve and renewal fund, and the balance of £598. 8s. 1d. carried forward to the next year's account.

"Your Directors are glad to be able to announce the completion of the conversion of the steam worked tramway, between Wednesbury, Darlast

Hosted by Google

Walsall and Bloxwich, into a system of tramways worked electrically by the overhead system of wires, and these lines (7½ miles) were opened for traffic on the 1st ult. The work appears to be satisfactorily executed upon sound principles, but your Directors must emphasise the long and what appears to be the unreasonable delay on the part of the contractors in completing the work. The prescribed penalties for the six months delay, although amounting to a considerable sum, do not in the opinion of your Directors more than represent the loss sustained by the Company, and as at present advised such penalties can be rigidly enforced.

"Your Directors have during the past year again approached the Birmingham Central Tramways Company in the hope that a through service into Birmingham might be arranged, but the Directors of that Company declined on any terms to grant running powers over their lines to this Company, but are, however, willing to continue their service of cable cars from the terminus of their line at Handsworth to Carter's Green, West Bromwich, a distance of nearly 2¾ miles of route, in the event of the conversion of this Company's lines between these points as a cable line, and your Directors having satisfied themselves that such an arrangement would be productive of mutual profit are now arranging for an agreement. It is hoped that a definite statement on this subject may be made at the meeting. The Directors will do all in their power to effect an arrangement which will not only be immediately profitable to this Company, but will also remove the present acute difficulties with the Corporation of West Bromwich and the Handsworth Local Board respecting the use of steam, the power to use which ceases at an early date."

W. T. Henley's Telegraph Works Company (Limited).

The following is the report of the Directors, to be presented at the ordinary general meeting of the Company, to be held at the Cannon-street Hotel, London, E.C., on Friday next, the 17th inst., at noon :—

The accounts for the year 1892 show a net profit of £15,456. 2s. 10d., after charging interest on the Mortgage and Debentures, and writing off £3,500 for depreciation of machinery and ship gear. Adding £21,731 0s. 3d. brought forward from last year, and deducting £808. 14s., the half-year's dividend to June 30, 1892, paid in October, on the Preference shares, there remains a disposable balance of £36,378. 9s. 1d. The Directors have added £18,545. 1s. to the reserve fund, and they propose the payment of a further half-year's dividend on the Preference shares at the rate of 7 per cent. per annum, and a dividend for the year at the rate of 5 per cent. free of income-tax, on the ordinary shares, leaving a balance of £13,425. 9s. 4d. to be carried forward.

Of the £30,000 "B" Debentures created in 1891, £14,000 were paid off during the past year, and the Directors purpose to pay off immediately a further £4,000, which will reduce the amount of these debentures to £12,000.

The general business of the Company in the manufacture of electric light cables, telephone cables, &c., has been satisfactory, and a considerable quantity of submarine telegraph and mining cables has been constructed for the British and foreign Governments. A cable has been manufactured and laid between the Bahamas and the coast of Florida (U.S.A.), and a repair of one of the Western Union Telegraph Company's cables, in the vicinity of New York has been effected. It is interesting to note that no fault has been reported in any of the submarine telegraph cables laid by the Company since 1888.

Numerous and important improvements have been made, and are still in progress in the machinery and buildings of the North Woolwich works, including the erection of new buildings for insulating the cores of submarine cables with gutta percha. The machinery in these buildings will be driven by electric motors, and the Company will then possess the most perfect workshop of its kind in the world. A branch establishment has been opened during the current year at Melbourne (Australia).

The Directors who retire on this occasion are Mr. Sydney Gedge and Mr. R. J. Jenkins, C.E., and being eligible, they offer themselves for re-election. The meeting will appoint auditors for the ensuing year.

NEW COMPANIES, STATUTORY RETURNS, &c.

BRITISH ELECTRIC LIGHT COMPANY (LIMITED).—The annual return of this Company, made up to January 3, 1893, has been filed. The Company was registered on October 4, 1878, with a capital of £100,000, in £10 shares, and at the time of making up 8,640 of these shares were taken up, 1,144 shares have been issued as fully paid, while upon the remaining 7,496 shares the full amounts have been called and all calls (£74,960) paid.

EASTERN TELEGRAPH COMPANY (LIMITED).—The annual return of this Company, made up to February 9th, 1893, has been filed. The nominal capital is £4,700,000, divided into 400,000 ordinary and 70,000 preference shares of £10 each. 469,988 shares have been taken up, the full amount called, and all calls (£4,699,880) paid.

FOWLER, LANCASTER, AND CO. (LIMITED).—At meetings held on January 17th and February 13th a resolution was passed and confirmed that the Company be voluntarily wound-up. Mr. James Rhodes, chartered accountant, Waterloo-street, Birmingham, has been appointed liquidator.

BIRMINGHAM TELEGRAPH FACTORY (LIMITED).—At a meeting held on February 13th it was resolved to voluntarily wind up the Company, and Mr. James Rhodes, chartered accountant, Waterloo-street, Birmingham, was appointed liquidator.——In the Chancery Division on Friday last, Mr. Jenkins applied to Mr. Justice Kekewich on behalf of Messrs. Fowler, Lancaster and Co. (Limited) for the appointment of a receiver in Birmingham Telegraph Factory (Limited) now in liquidation. His clients were debenture holders for £3,000. The Company went into voluntary liquidation on February 13th last. His Lordship allowed the person appointed by the plaintiffs to act as receiver until Tuesday next.

W. T. HENLEY'S ELECTRIC LIGHT AND POWER COMPANY (LIMITED).—The final winding-up meeting of this Company was held on January 16th, when an account, showing the manner in which the winding-up had been conducted and the property disposed of, was laid before the meeting.

CITY NOTES, &c.

BRAZILIAN SUBMARINE TELEGRAPH COMPANY (LIMITED).—The Directors of this Company have declared an interim dividend of 3s. per share, or at the rate of 6 per cent. per annum (free of income-tax), for the quarter ended December 31, 1892, and payable on the 25th inst. The books of this Company will be closed from the 18th to the 24th inst., both days inclusive.

CALLS DUE.—*March 15th*, City of London Electric Lighting Company (Limited), £2 on 20,000 £10 Cumulative Six per Cent. Preference Shares. *March 15th*, Electric Construction Corporation (Limited), £3 on 10,000 £10 Second Mortgage Debentures. *March 15th*, National Telephone Company (Limited), final £1 on 90,950 £5 per Cent. Non-Cumulative Third Preference Shares. *March 31st*, Scottish House-to-House Electricity Company (Limited), final £1. 10s. on 6,000 £5 Ordinary shares.

CITY AND SOUTH LONDON RAILWAY COMPANY (LIMITED).—The traffic receipts for the week ended March 5th were £929, as against £893 for the corresponding period of last year, being an increase of £36. The total receipts for half-year amount to £8,672 against £7,632 in the corresponding period of 1892, being an increase of £1,040.

COMMERCIAL CABLE COMPANY.—The report of this Company states that the gross earnings for the year 1892 amounted to $1,890,377, and the net revenue to $1,099,587, the latter showing an increase of $14,263 as compared with 1891. Quarterly dividends of 1¾ per cent. each have been paid, absorbing $540,120, and debenture bonds to the amount of $500,000 were redeemed on January 15th last, thereby reducing the total amount of bonds outstanding to £80,000. In order to provide for the laying down of a third cable it has been decided to offer to the shareholders, for subscription at par, 19,290 shares out of 22,840 shares now unissued.—A quarterly dividend of 1¾ per cent. has just been declared, payable on April 1st.

DIRECT SPANISH TELEGRAPH COMPANY (LIMITED).—The Board have decided to recommend the payment of the dividend at the rate of 10 per cent. per annum on the preference shares and a dividend at the rate of 4 per cent. per annum (free of income-tax) upon the ordinary shares, both for the half-year ended December 31st last.—The traffic receipts for the month of February were £1,808, against £1,865 for the corresponding period of last year.

DIVIDENDS.—Bell's Asbestos Company (Limited) have declared a dividend of 5s. per share for half-year to December 31st last, payable on the 18th instant, and making 7½ per cent. for the year.——Bolckow, Vaughan and Co. (Limited) have declared a dividend of 2½ per cent. for the year ended December 31st last.——Brown and Bayley's Steel Works (Limited) have declared a dividend of £1. 5s. per share, making 20 per cent. for the year ended December 31st last.——Muntz's Metal Company (Limited) have declared a dividend of 5s. per share, making 10 per cent. for the year ended December 31st last.——Scottish Boiler Insurance and Engine Inspection Company (Limited) have declared a dividend of 2s. per share for the year 1892.——A. and J Stewart and Clydesdale (Limited) have declared a dividend of 9 per cent. for the half-year to December 31st last, making 7½ per cent. for the year 1892.——United Alkali Company (Limited) have declared a dividend of 6 per cent. for the year 1892.——United Asbestos Company (Limited) declare a dividend of 5s. per share for the year ended December 31st last, payable on the 15th inst.

GREAT NORTHERN TELEGRAPH COMPANY.—The traffic receipts of this Company for February amounted to £20,400, and from January 1st to February 28th to £41,200. In the corresponding months of 1892 and 1891 the amounts were £40,800 and £41,600 respectively.

PHOSPHOR BRONZE COMPANY (LIMITED).—At the annual general meeting recently held at the Bridge House Hotel, London, S.E. (Mr. James Rock in the chair), the report of the Directors and the accounts were adopted and dividends of 5 per cent. on the preference shares, and 1¼ per cent. on the ordinary shares were declared, to be paid on or before March 31st next. £1,000 was added to the contingency fund, and £134. 1s. 2d. was carried to new account. Mr. Richard Gamble was re-elected a Director, and Mr. Robert Payne, F.C.A., was re-elected auditor.

STOCK EXCHANGE NOTICES.—The Stock Exchange Committee have appointed Tuesday next, the 14th inst., as a settling day in the City and South London Railway Company's Perpetual Five per Cent. Preference Shares, Nos. 1 to 7,000, and have ordered these securities, and £30,000 additional stock, to be quoted in the Official List. Application has been made to the committee to allow the further issue of 4,120 ordinary shares of £5 each, Nos. 454,748 to 458,867, of the National Telephone Company (Limited), to be quoted in the Official List.

WESTERN UNION TELEGRAPH COMPANY.—The Directors' statement for the March quarter shows an estimated surplus, after the payment of

Hosted by Google

the customary dividend of 1¼ per cent., of $247,127. General T. T. Eckert is to be appointed president, in place of the late Dr. Norvin Green.

WESTERN AND BRAZILIAN TELEGRAPH COMPANY (LIMITED).—The traffic receipts for the week ended March 3, 1893, after deducting 17 per cent. of the gross receipts payable to the London Platino-Brazilian Telegraph Company (Limited), were £3,816.

WEST INDIA AND PANAMA TELEGRAPH COMPANY (LIMITED).—The receipts for the two weeks ended February 28th were £2,443, as compared with £2,635 for the corresponding period of last year.

WHOLESALE AND EXPORT ONLY.

"SILENT" ENGINES (CHANDLERS' PATENTS)

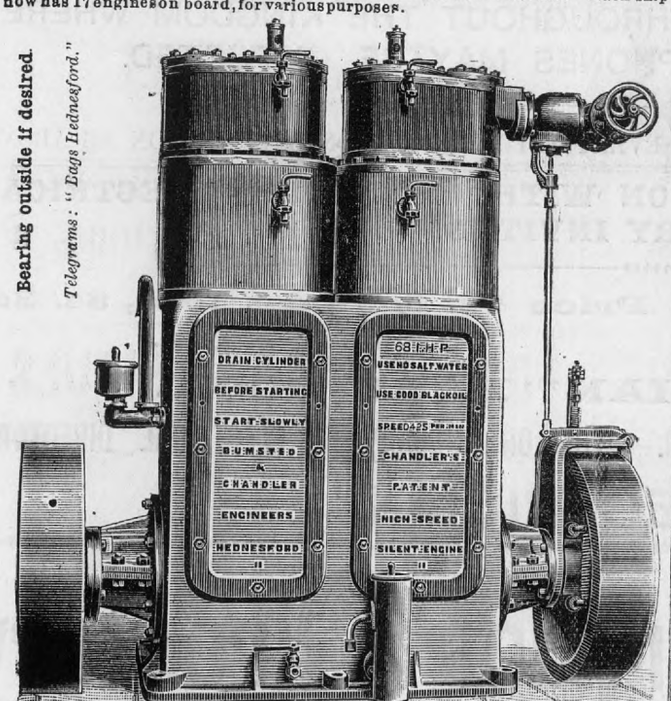
FOR ELECTRIC LIGHTING.

Made in 20 SIZES, with one or two cranks, from 2 to 200 Horse-power, **simple compound or tri-compound, giving the highest economy,** at speeds suitable for coupling direct to dynamos for THEATRE-LIGHTING, for CENTRAL STATIONS, for SHIP-LIGHTING, and TRAIN-LIGHTING.

Electrical Firms and Shipowners may place perfect confidence in these Engines, as they are the most durable ever introduced, and as economical as any other high-class engine. After prolonged and severe tests (which caused the engines of other makers to break down) these engines were selected for use on ss. "*Teutonic*"; these worked so satisfactorily that they were also selected for ss. "*Majestic.*" Each ship now has 17 engines on board, for various purposes.

Bearing outside if desired.

Telegrams: "Dags Hednesford."



One Electrical Firm has ordered no less than 40 engines in two years, another firm 82, another firm 19, another firm 16, another firm 14, and a large number of other firms have sent many repeat orders. Twenty of the British India Steam Navigation Company's Steamers are lighted by these Engines. All this goes to prove that the Engines are reliable and highly satisfactory. Many are working without lubrication to Cylinders. NO AIR NOR OIL CAN POSSIBLY PASS AWAY TO CONDENSER.

Every part can be got at comfortably when the door is removed.

Speed adjustable while Engine is running. Requires less care than any other Engine known, and uses less oil. **NO OIL IS LOST.** Engine easily understood. No complications Inside. Constructed to stand hard work. The Patent "Safety" Governors are Extremely Sensitive. They are mounted on the Crank Shaft and require no belt to drive them, and are everlasting.

Letter from Superintending Engineer of Sixteen Steamers with these Engines on board, says:—"*All the Engines are working very satisfactorily.*"

CHANDLER CROMPTON COMBINED COMPOUND PLANT.

For SHIP LIGHTING and TRAIN LIGHTING, as supplied to the Cape Government Railways and many Steamers.

LECLANCHE-BARBIER PATENT CYLINDRICAL AGGLOMERATE BATTERIES.

ALSO

ACCLOMERATE BLOCK AND POROUS POT BATTERIES. LECLANCHE ACCLOMERATE BLOCKS OF ALL SIZES.

THE LECLANCHÉ BARBIER CYLINDRICAL AGGLOMERATE WET CELL is the newest and most efficient form of Leclanché Battery. It is an open cell, all parts being instantly accessible, but so arranged as to render it practically a sealed one, with no evaporation or creeping salts.

No. 1.—E.M.F. 1·5 volts, I.R. 0·4 ohms No. 2.—E.M.F. 1·5 volts, I.R. 0·8 ohms.

THE LECLANCHÉ-BARBIER CYLINDRICAL AGGLOMERATE DRY CELL possesses all the advantages of the wet one, with the special feature that not being sealed up (like all other dry batteries), any decrease in its E.M.F. can be at once restored by letting it absorb a little ammoniacal solution. The user can thus constantly maintain its efficiency at a trifling cost.

No. 1.—E.M.E. 1·5 volts, I.R. 0·5 ohms. No. 2—E.M.F. 1·5 volts, I.R. 0·6 ohms.

SOLE AGENT FOR GREAT BRITAIN AND THE COLONIES—

THE ELECTRICAL and GENERAL ENGINEERING COLLEGE and SCHOOL OF SCIENCE.

PENYWERN HOUSE

2, Penywern Road, EARL'S COURT, S.W.

Principal: G. W. de TUNZELMANN, B.Sc., M.I.E.E.

The Complete Courses qualify Students for entry into Electrical and other Engineering Work.

The First Year's Course is arranged to qualify for entry into Cooper's Hill, the Central Institution, and the Royal School of Mines.

Extensive Laboratories, Dynamo Room, &c.

Students are regularly sent to the College by leading Engineers and Scientific Authorities, whose names are given in the Prospectus.

THE LATEST ELECTRICAL NOVELTY.

ROBERTSON'S PATENT ELECTRIC CIGAR LIGHTER.

Size 6¾in. by 6¼in.

Price (packed in box, post free) **21s.**

Is absolutely safe. Machine complete in itself.
Generates its own Electricity.
So simple a child can work it.
Lights instantaneously on pressing knob.
3,000 lights at the cost of 6d.
Lasts a lifetime.

SHOULD BE IN EVERY SMOKING-ROOM.

These Electric Lighters are made of the best quality nickel-plate, and are of first-class workmanship.

NOTES.

The question which Prof. Unwin asks at the end of the second paragraph of the letter which will be found in our correspondence columns is, perhaps, the most important question of the day for electrical engineers. It is only during the last two years or so that they have realised the serious difference between the cost of a continuous load and of an ordinary electric-lighting load. Prominence was given to this question by the late Mr. Willans, by comparing the coal consumption at central stations with the consumption found during full-load tests. We are not disposed to accept the analysis of the Bradford figures for two reasons. In the first place, the accounts of Corporations cannot be compared with those of limited liability companies; for several of the various items to which Prof. Unwin alludes are treated in a different manner in the two cases, and the actual expenditure and cost, even if the books were kept in the same way, could not be compared. Interest on capital, redemption, insurance, depreciation, office rent, clerical expenses, collecting expenses, works in the streets, cartage, and other matters cost less to a Corporation than to a company; and herein lies the sole advantage that we can discover in allowing a Corporation to carry on the business of electrical supply, and in many cases, to seven or eight times.

It is possible, as was pointed out by Mr. Garcke in the discussion following Mr. Shoolbred's Paper before the Society of Arts, for a Corporation to present a favourable account of their doings, since they have great facilities for distributing their expenditure over the accounts of different departments; on the other hand, there is no trade bias. When it comes to discarding "half of the cost under the headings 'repairs and maintenance,' and 'depreciation,' because there appear to be included in these items more than is fairly chargeable to cost of power," we are getting a long way from the simple facts.

The Bradford coal is cheap, but is said to have but low calorific value. The cost of cartage to some of the London stations is, on the other hand, expensive. The only thing that can be compared with certainty would be the steam consumption per unit, or per horse-power-year. It is practically impossible to collect statistics on this point. When the Board of Trade returns for this year are complete, we shall make a careful analysis of the costs, as we did last year, and if the accounts of the provincial companies can be brought into any sort of common form, we shall attempt to examine them also, but hitherto nothing worthy of being called a comparison has been possible. There seems to be a general impression among the engineers of successful companies, that an ordinary load factor runs up the cost to at least three times that of a supply with a load factor of unity.

The system of rebates adopted by the London Electric Supply Corporation, unlike certain others, appears to encourage the small consumer, and to keep the ratio of lamps used to lamps fixed somewhere about unity. It is, moreover, easily understood, though, perhaps, the real value of the concession is not to be appreciated without a little calculation. The rebate begins when the consumption per 8 c.p. lamp exceeds 35 units per annum. At 32 watts per lamp, this means about 1,100 burning hours, excluding Sundays but including fogs; this is equivalent to each and every lamp being alight from dusk to 9 p.m. all the year round. If three-quarters of the lamps are turned out at 8 p.m., the remainder will have to burn till midnight, if a first taste of the rebate is to be enjoyed. The exact amounts of the rebates will be found in another column.

Whenever a public body succeeds in performing the feat popularly known as getting people's backs up, it may be predicted with some degree of certainty that all its subsequent acts will meet with an opposition altogether out of proportion to their intrinsic merits or demerits. That the London County Council has attracted to itself the dislike of a powerful section of the community is not to be gainsaid, and this circumstance, added to the fact that Mr. Pickersgill, with true County Council maladroitness, succeeded in ruffling the feelings of sticklers for Parliamentary etiquette, will account for the smart rebuff sustained by the County Council on Thursday last week in its attempt to secure the insertion of a purchase clause in the City and South London Railway Bill.

It is satisfactory to note that the confiscatory tendencies of the County Council have been subdued, and that it is now only anxious to acquire the electric railways "on *fair* conditions at the expiration of a certain term of years," the term to be such an one as would have "no effect on the financial prospects of the companies." It is reassuring, moreover, to be officially informed that there is "no wish on the part of the London County Council to crush out legitimate commer-

Hosted by Google

cial enterprise." In face of such an attitude of sweet reasonableness, and in view of the fact that Manchester, Liverpool, Glasgow, and other large towns possess powers of purchase similar to those asked for by London, the refusal of Mr. PICKERSGILL's demand by an overwhelming majority can only be accounted for on the hypothesis propounded above.

WHAT seems to us one of the gravest of the objections advanced against municipalisation of this, that, and the other, was adverted to in this debate; we refer to the inadvisability of a public body directly employing a large percentage of its own constituents. From the point of view merely of the financial promotion of these long-delayed electric railways, the rejection of the County Council's proposals is, of course, an unqualified good. We trust that these railways will now be pushed forward on a sound financial basis, for the results so far achieved by the City and South London Railway are, when rightly interpreted, decidedly encouraging.

IN a recent number of *La Lumière Electrique* is described a special mode of winding transformers, the object of which is to diminish the loss of energy occurring on light loads. The core losses of transformers do not depend upon the output, and form the most important part of the losses when the load is small. They may be reduced by lowering the induction at which the iron is worked, and this end is secured by Messrs. SIEMENS and HALSKE by winding each coil of the transformer in two equal sections, and arranging these sections in parallel when the transformer is heavily loaded, and in series when the load is light. A special switch is arranged for altering the connections. In this manner the induction density used with small loads is only half that which is employed when the output is large, and the core losses are diminished in about the ratio of 5 to 2. But although a great saving is brought about in this way, it is accompanied by an increase in the coil losses, caused by the fact that the resistance of each coil has been quadrupled by rearranging the connections; and, until the output of the transformer is reduced to less than half full load, no real saving can be effected by this device. It would, no doubt, if properly used, bring about an important increase in the all-day efficiency of transformers; but it is hardly likely that the ordinary householder will appreciate the advantage of an attachment which has no apparent effect on the brightness of the lights; while, if the transformers are collected in sub-stations, no such device is necessary, since there is then no need to work any transformer at less than half load.

AMONGST "practicians," one of the best-abused of modern movements is that in favour of technical education. It is, therefore, a relief to find that such an old engineering hand as SIR FREDERICK BRAMWELL can see at least one potential advantage in the increased opportunities at present afforded for learning the science underlying most trades and professions. In an interestingly-anecdotal inaugural address recently delivered at the opening meeting of the current session of the Goldsmiths' Institute Engineering Society, SIR FREDERICK predicted that one great advantage of instruction in principles would be that inventors of the "flat-earth" and "perpetual-motion" order would, in process of time, become extinct. For our own part we are not so sanguine. To attempt impossibilities will always be the destiny of an appreciable proportion of mankind; and, if authentic statistics were available, we feel sure that it would be found that 90 per cent. of those who attempt the impossible do so by way of the Patent Office. A man possessed of an idea is not to be turned aside by such a venial error as an infraction of the law of conservation of energy. This propensity, in turn, has its compensation in the occasional upsetting of ostensibly well-established "laws" by those who refuse to take them for granted.

Dundee.—The "inauguration" of the municipal electric lighting station took place on Tuesday evening last at seven o'clock.

Chicago Exhibition.—The *Journal* of the Society of Arts for March 10th contains the regulations governing awards at the Chicago Exhibition.

Alloys.—Prof. Chandler Roberts-Austen's Cantor Lectures on "Alloys" will be printed in the *Journal* of the Society of Arts during the summer recess.

Electric Light Wiring.—The chief of the Electrical Department of the Philadelphia Fire Underwriters' Association is now in Europe to inquire into and examine the safeguards used for the protection of theatres lighted by electricity, &c.

Electrical Inspectors.—Inspectors are much *à la mode* in these days. In Switzerland they have an "Inspector of Strong Currents," whose duty it is to see that electrical currents, other than telephonic and telegraphic, are kept in the way they should go.

Electric Power Charges.—At Chambéry, in Savoy, M. Gacon, the electric light and power concessionaire, is to charge £18 per annum for a 1-horse motor, £10 per annum for a $\frac{1}{2}$-horse motor, £6 per annum for a $\frac{1}{4}$-horse motor, £3 per annum for a $\frac{1}{8}$-horse motor, £1. 10s. per annum for a $\frac{1}{16}$-horse motor.

Electrical Bills in Parliament.—On Thursday last week in the House of Lords the Baker-street and Waterloo Railway Bill was read a third time, and, after amendments had been inserted, was passed.—On Wednesday last the Kensington and Knightsbridge Electric Lighting Company Bill was read a second time in the House of Commons.

The Electric Lighting of the Houses of Parliament.—The First Commissioner of Works intends to ask for a vote of £12,000 to extend the electric-lighting arrangements in both Houses of Parliament. Only £1,600 will, however, be expended in the coming year. The cost of electric lighting last year in the House of Commons was £1,800.

The Electrical Utilisation of Water-power.—A concession, says *Industries*, has been recently granted to utilise the water-power available at the Todten Mountain, near Aussee, in Styria. About 8,000 H.P. will be obtainable, which will be utilised in the production of electrical energy for industrial purposes. The State has a financial interest in the undertaking.

The Lighting of the Embankment.—The London County Council has approved of the appropriation of the piece of land adjoining the Charing-cross District Railway Station for the purposes of a generating station in connecting with the electric lighting, for which the Council is seeking powers in its General Powers Bill of this session, of the Victoria Embankment and ornamental gardens, and the Westminster and Waterloo bridges.

Liverpool Overhead Railway.—This line was opened to the public on Monday, March 6th. The number of passengers

Hosted by Google

carried on that day was 17,541, and the receipts were £164. 3s. The Company expect to be able to commence their five minutes' service shortly (at present they are content with a ten minutes' service) and also to run from 5 a.m. to 9 p.m., instead of from 7 a.m. to 7 p.m., as at present. Already there are loud complaints of overcrowding.

Hertford.—At a meeting of the Town Council, held on Thursday last week, a report by the Electric Lighting Committee was presented, recommending the adoption of an alternating current system, with transformer sub-stations and gas engines burning Dowson gas, at an estimated cost of £5,800. It is proposed to use two 35-kilowatt dynamos, mechanically coupled together, in order to obtain steady running. After some discussion it was decided to consult a leading electrical engineer.

Kensington Vestry.—At a recent meeting of this Vestry a letter was received stating that the Kensington and Knightsbridge Company were prepared to complete a supply of electric current to the district within a year and a-half. The Law and Parliamentary Committee reported in favour of the arrangement, but Mr. Braye moved that the matter be referred back. This was negatived. Later on, it was resolved, on the motion of Mr. Saunders, Q.C., that the question of the Vestry taking the lighting into its own hands be referred to a Committee.

Woodhouse and Rawson United.—When the late Mr. Otway Woodhouse, senior partner in the firm of Woodhouse and Rawson, died, shortly after the transfer of the business of that firm to a private limited company, the value of his estate, says the *Statist*, was sworn at £1,000, which was afterwards increased, presumably in respect of his share of the proceeds of sale, to £2,000, representing, apparently, one-half of the original capital of the parent business, of which the various existing Woodhouse and Rawson, Elmore, and Kensington Stores Companies are the offspring.

The Telephone in Lancashire.—The National Telephone Company's system in North-East Lancashire is, says the *Birmingham Daily Post*, threatened with temporary paralysis. A firm of Blackburn brewers, owning public houses in Blackburn, Burnley, Preston, Accrington and Darwen, over which the trunk wires to Manchester, Liverpool, and other towns have been carried, have made a demand for way-leave, with which the Company have refused to comply. As a consequence they have been ordered to remove the trunk wires and also 300 wires belonging to private subscribers.

Société Internationale des Electriciens.—The following is the list of the new "bureau" of this Society, which is to be elected on April 5th next for office in 1894:—President: M. Postel-Vinay. Vice-Presidents: MM. Hospitalier and Picou. General Secretary: M. Hillairet. Secretaries: MM. Gaston Roux, Thomas, and Violet. Treasurer: M. Dumoulin-Froment. Members: MM. Arnoux, d'Arsonval, Barbier, Benard, Bergon, Bordet, Bovet, Delaunay-Belleville, Gauthier-Villars, Géraldy, Javaux, Leblanc, Monnier, Saladin, Tresca, Lazare Weiller, and Williot. Auditors: MM. Armengaud (Junr.), Berthon, and Masson.

Obituary.—On the arrival at Hastings of the last train from London on Thursday night last week, the end window of a third-class carriage on the down side was found smashed, and the glass scattered on the seat. Subsequently the body of a man was found on the line between Frant and Tunbridge Wells. The body was identified as that of Mr. E. T. Mercer, manager of the Hastings and St. Leonards-on-Sea Electric Light Company. He left Hastings for London on business of the Electric Light Company on Thursday morning. He is supposed to have opened the door and been knocked backward against the side window.

The City and South London Railway.—In reply to Mr. A. C. Morton, Mr. Mundella stated in the House of Commons on Thursday last week that the Board of Trade had from time to time received complaints of overcrowding on the City and South London Railway, and had communicated with the Company. The Company stated that they were using every effort to meet the press of traffic which occurred for about an hour every morning and evening. To enable them to do this additional sidings were being constructed, and an application was now before Parliament for power to construct a duplicate line from the Borough to the City.

The London Electric Supply Corporation.—The following special notice of reduction in charge has been issued by this Company:—

From April 1st next the Corporation's standard charge for electrical energy will be 6d. per Board of Trade unit. All customers will also be entitled to the benefit of the following sliding scale, extending from the standard rate to 5d. per unit, based on their consumption of energy. Where the consumption per 8-c.p. lamp exceeds:—

35 units per annum ...	5¾d.	45 units per annum ...	5¼d.
40 „ „ ...	5½d.	50 „ „ ...	5d.

Accounts will be rendered at 6d. per unit, the deductions due under the sliding scale being allowed in the account rendered for the last quarter of the year.

Brighton.—The agenda at yesterday's meeting of the Town Council contained the accounts of the Corporation Electric Lighting undertaking for the year ended December 31, 1892. The revenue account shows a total expenditure of £2,457. 15s. 3d., the expenditure on generation being £1,643. 6s. 11d. The income is £4,687. 4s. 2d., divided as follows: Electricity sales, £4,543. 4s. 2d.; meter rents, £139; and work executed for customers, £5. Of the £2,233. 10s. 4d. gross profit, £2,221 6s. 1d. is transferred to net revenue account, and £12. 5s. 3d. is carried forward. The expenditure in the net revenue account is £1,238. 4s. 4d. interest, and £983. 1s. 9d. to sinking fund.

Cable Interruptions and Repairs.—

	Interrupted.		Repaired.
Cayenne-Vizeu.....	September 24, 1892.	...	March 10, 1893.
Accra-Grand Bassam	March 13, 1893.	...	March 15, 1893.

Cable actually interrupted:—

Gibraltar-Tangier ..... February 18, 1893.

According to a telegram from Teneriffe, some excitement has been caused there by the suspicious movements in the neighbourhood of a foreign war vessel, and a Spanish gunboat has been sent out to keep the stranger under observation. They are evidently unaccustomed to cable-repairing ships in these waters, as it appears to be the Eastern Telegraph Company's ss. "Mirror," at work near that island, which has caused the commotion.

Swedish Telegraphic Statistics for 1892.—During 1892 the number of paid telegrams transmitted by the Swedish State Telegraphs amounted to 1,866,692, against 1,849,533 the previous year, an increase of 0·9 per cent., the greater part of which meagre increase is due to foreign traffic. The receipts for these telegrams, so far as Sweden is concerned, amount to about £70,000, and show a decrease of some £660 compared with 1891. This decrease in the receipts may in a large measure be set down to the continuous diminution in the average number of words per message. About 70,000 telegrams were transmitted during 1892 free of charge, about half of these being meteorological. As to Press telegrams, transmitted at reduced rates, the number in 1892 was 23,847, which shows an increase of between 2,000 and 3,000 as compared with the previous year.

Electric Lighting at the St. Lazare Terminus.—In 1889 400 H.P. electric light plant was laid down by M. Cance to supply current to the St. Lazare terminus of the Chemin de Fer de l'Ouest. This plant having proved unequal to the increased demand, a new 770 H.P. generating station was erected a little more than a quarter of a mile off. This station is now supplying current to 250 arcs and 2,600 incandescents. The plant comprises five Belleville boilers, five 140 H.P. high-speed Corliss engines, by Lecouteux and Garnier, and one 70 H.P. vertical engine, and eleven shunt-wound Gramme dynamos, giving 550 amperes at 80 volts. Distribution is carried out by a ring main. The arc lamps are fitted with diffusing globes, and take 25, 8, and 6 amperes. The average illumination on the platforms is 1·27 bougie metres, or 0·127 candle-feet approximately.

Fire at a Chicago Electric Lighting Station.—A few weeks ago a fire was discovered in the feeder pit under the engine room of the Adams-street station of the Chicago Edison Com-

Hosted by Google

pany. The fire was not a serious one, and could have been easily got under by the *employés* of the station, but an alarm was sent to the fire department. This proved very unfortunate. When the firemen came they were asked not to use water on the feeders until the station could be shut down. They were not, says the *Western Electrician*, to be instructed by any mere electricians, however, and insisted on deluging the cables with water despite the angry remonstrances of the station people. There was instantly a total short-circuit, flames mounting the wall of the engine room, and the entire plant was incapacitated, every light on the company's circuits going out. The firemen had put out the fire, but the remedy was many times worse than the disease.

The Relative Corrodibility of Pure and Alloyed Lead.—This subject has, says the *Engineering and Mining Journal*, lately received considerable attention from Dr. Lunge. After conducting a great number of experiments with various alloys, he draws the following conclusions:—1. There is no difference in the cold between the actions of sulphuric acid on pure and antimonial lead, when the admixture of antimony does not exceed 0 2 per cent. When the acid is warm, the difference in favour of pure lead is more marked. 2. The action of nitrous vitriol is in all cases stronger when air has access than when not; and is always greater than pure vitriol. 3. The addition of a small percentage of copper to the lead does not increase its power to resist the attacks of sulphuric acid when the temperature is below 200deg. C.; when the temperature is above 200deg. C. the addition of 0 1 to 0·2 per cent. of copper is advisable, though its effect is not very marked.

The Cable Ship "Norseman."—The new "Norseman," just built for the Western and Brazilian Telegraph Company, made her trial trip on Tuesday last. A large party embarked at Tilbury, and were carried at the guaranteed speed of 14 knots to within sight of Margate. Unfortunately, on the return journey a slight mishap occurred to the machinery, and a rather long stoppage had to be made. The "Norseman," which was constructed by Messrs. Ramgate and Ferguson, of Leith, is 235ft. long between the perpendiculars, has triple-expansion engines, and is furnished with all the most modern machinery to execute the work she is intended for on the coast of Brazil. Throughout, the vessel is fitted with electric light, and the accommodation for both officers and men is especially commodious and comfortable. Major Wood, the Managing Director, was particularly anxious that the ventilation should be as perfect as possible, and his ideas have been satisfactorily carried out by the marine architects (Messrs. John Thomson and Son). Captain Lacy (the commander) was cordially complimented upon the splendid capabilities shown by the "Norseman" on her trial trip.

The National Telephone Company and the Leeds Corporation.—The Leeds Corporation in their Bill this Session propose to take power for acquiring the tramways and to work or lease them. The National Telephone Company have presented a petition against the Bill, and before the Court of Referees, presided over by Mr. Sheress Will, the Corporation contested the *locus standi* of the Company Mr. Pembroke Stephens, Q.C., appeared for the Leeds Corporation, and Mr. Cripps, Q.C., for the Telephone Company. Mr. Cripps submitted that the question had already been disposed of, inasmuch as the Court had given a *locus standi* to the Company against the Blackpool Improvement Bill and other Bills, the circumstances of which were on all fours with the present case. On the other hand, Mr. Pembroke Stephens submitted that the cases differed, and that since the decision in the Blackpool case it had been shown that the Telephone Company could protect themselves without the insertion of any clauses in the Bills. The Court, however, without calling upon Mr. Cripps to reply, decided to allow the *locus standi* of the Company against that portion of the Bill relating to the tramways. Mr. Chandos Leigh, the Speaker's Counsel, appealed to the representives of the Leeds and Blackpool Authorities to agree upon an identical clause for the protection of the Telephone Company, and the representative of the Company stated that his clients were perfectly willing to accept the clause suggested by the Board of Trade in 1889.

Forthcoming Books.—The following are a few of the books of scientific interest announced as about to be published:—*The Electrician* Printing and Publishing Company (Limited) will shortly publish the following: "Electromagnetic Theory," by Oliver Heaviside; "A Pocket-Book of Electrical Engineering Formulæ," by W. Geipel and H. Kilgour; "Submarine Cable Laying and Repairing," by H. D. Wilkinson; "Drum Armature Winding, and Commutators," by F. M. Weymouth; and "Electricity as a Motive Power," by Albion T. Snell. "The Metallurgy of Iron and Steel," by the late Dr. John Percy, F.R.S., a new and revised edition, with the author's latest corrections, and brought down to the present time by H. Bauerman, with illustrations (Mr. Murray). Messrs. Longmans announce:—"Telephone Lines and their Properties," by Prof. W. J. Hopkins; "A Treatise on Electricity and Magnetism," by G. W. De Tunzelmann, in 2 vols. Among Messrs. Macmillan and Co.'s announcements are:—"A Uniform Edition of Prof. Huxley's Essays," in 6 vols., comprising Lay Sermons, Addresses and Reviews, Critiques and Addresses, Science and Culture, American Addresses, Man's Place in Nature, &c.; "Elementary Treatise on Modern Pure Geometry," by R. Lachlan; "Exercises in Euclid," by Wm. Weeks; "Utility of Quaternions in Physics," by Alexander McAulay. In the Clarendon Press list are:—"A Supplementary Volume to Prof. Clerk Maxwell's Treatise on Electricity and Magnetism," by Prof. J. J. Thomson, F.R.S.; "A Manual of Crystallography," by Prof. M. H. N. Story-Maskelyne, F.R.S.; "Analytical Geometry," by W. J. Johnston; "A Treatise on the Kinetic Theory of Gases," by Dr. H. W. Watson, new edition; "An Elementary Treatise on Pure Geometry," with numerous examples, by J. W. Russell. Messrs. Percival and Co. give notice of:—"Electricity and Magnetism," by L. Cumming; "Heat," by G. Stallard; "Light," by H. P. Highton; "Mechanics" (treated experimentally), by L. Cumming; "Practical Physics," an introductory handbook for the physical laboratory, in three parts, by Prof. W. F. Barrett; Part II. Heat, Sound, and Light; Part III. Electricity and Magnetism, Electrical Measurements.

The St. Louis Arc-Light Station.—In the fourth article of the interesting series on "The Electrical Side of St. Louis," now in course of publication in the *Electrical World*, a well-illustrated account is given of the great arc light station of the Municipal Electric Light and Power Company. This station, which is by far the largest of its kind in the world, is managed by Mr. James I. Ayer. The arc-lighting plant comprises 63 60-light, 13 80-light, and 2 75-light machines, all of which, except the last two, are of the Wood type. The Wood arc-lighter is of the Gramme pattern, and normally supplies a current of 9·6 amperes. It is worked up to over 2,500 volts. Sparking at the commutator is mitigated by an auxiliary brush placed a few sections ahead of the working brush, and the volts are varied by varying the position of the brushes. The Company has now in operation 36 municipal arc-light circuits of a total length of 532 miles, ranging from 8 to 22 miles each, and averaging 15 miles per circuit, to which are connected 2,100 arcs. It has also 30 commercial arc-light circuits, aggregating 240 miles of wire, to which are connected 1,500 arcs. Thus the arc light circuits have a total length of 772 miles and supply current to 3,600 lamps. Steam is generated by 19 vertical boilers, and supplied to seven Hamilton-Corliss, each of 640 H.P., and one of 50 H.P. The seven large engines are each belted to a countershaft situated on the floor above, the seven sections giving a total length of 400ft. of 6in. hammered iron shafting. Each section is driven by a 48in. double belt running over a steel-rimmed 56in. pulley with 52in. face. The dynamos are situated on the floor above the countershafting, and each one can be thrown into or out of action by friction-clutches operated from the dynamo room. By means of a huge plug switchboard with flexibles and spring jacks any dynamo can be connected to any circuit, and any desired number of machines can be coupled in series. The bearings receive oil through a system of pipes; the oil is carried thence by drain-pipes to the filter in the basement, from which it is pumped to the fourth floor to be used again. The spent oil is filtered upward through water, sand, and charcoal. The Municipal Company, in addition to a Slattery alternating plant, also runs a 500-volt 300-H.P. plant.

ELECTRICITY AS A MOTIVE POWER.*

BY ALBION T. SNELL.

§1. The General Scheme of Electrical Transmission of Power.

Prime Source of Power.—The consideration of this part of the working plant belongs more properly to a treatise on prime motors; but the requirements of electrical work have introduced quite a revolution in the building of both steam engines and turbines, and probably a few hints as to the class of plant most suitable will not be unacceptable or out of place.

The dynamo is essentially a high-speed machine, one of the fundamental factors of both output and efficiency being a high peripheral speed of the armature. Practical considerations confine this to about 3,000 feet per minute; and hence, for a given output, economy of material and labour will limit the diameter and length of the armature so as to make the speed a maximum. Now the stationary engine of 15 or 20 years ago was, on the contrary, a slow-speed machine, *i.e.*, the flywheel made relatively few revolutions per minute, although the piston velocity may have been in some cases as high as 300 or even 400 feet per minute. The cylinders were of large diameter and long stroke, being designed to work with low boiler pressures. Therefore, when it became necessary to drive dynamos by this type of engine, difficulties arose in belting the dynamo pulley to the flywheel; and it soon became evident that the engine was in many ways unsuitable. Firstly, it was inefficient for the class of work; secondly, it governed badly; thirdly, it was costly in relation to its output; and, fourthly, it required foundations of a strength out of all proportion to the load. These weak points in steam-engine design were gradually forced on the notice of mechanical engineers by the introduction of the efficient and high-speed dynamo. But improvements were made before long. Boilers were built for higher pressures, enabling engines to be designed with smaller cylinders and to rotate at higher speeds. Next, governors were improved, and soon the tell-tale pilot lamp scarcely showed the variations of speed, and now it is by no means uncommon to find engines governing to within 2 per cent. or even less. Compound and triple expansion engines have now become general. The vertical type of engine, with inverted cylinders, is most in favour to-day for driving dynamos. It is used either single, compound, or triple, with or without condensers, according to output and circumstances. It is coupled direct or by belting, requires small foundations, gives a minimum of trouble, and is cheap and efficient. Compared with the beam or horizontal engines of from 20 to 30 years ago, it is as David to Goliath.

The change in boiler design has been equally remarkable. Fifty pounds to the square inch used to be considered a fair working pressure with boilers of the Lancashire type, now 80lb. is not uncommon; and with multitubular and water-tube designs 140lb. or even a greater pressure frequently occurs; and water-heaters, economisers, and mechanical stokers are being gradually appreciated. All these improvements, it is needless to say, tend to raise efficiency and decrease the running charges.

In choosing steam plant for an electrical transmission installation, therefore, the rules and precautions adopted in laying down a central station for lighting should be followed. First choose a convenient unit of power, *i.e.*, select the best size of dynamo to give the minimum work required during the twenty-four hours, and then if this be of convenient size keep to it as the standard, and simply multiply the unit as the work increases. If the minimum output be very small, it will probably be best to have a separate plant to deal with this part of the work, and to select a larger unit for the main installation. Having fixed the output of the dynamo, the size of the engine which has to run it, either direct or by belting, is easily determined; and the boiler power is also known. The boiler unit may be sufficient to run one or two engines; this will depend on their size, and cannot be definitely fixed without a knowledge of each case. The boilers should each be coupled with a stop-valve to the steam main, so that any boiler can have the fires banked or be shut down separately. One boiler and an engine and dynamo should be held in reserve in all large installations.

If water power be used, the turbine or water-wheel can advantageously drive the dynamo direct, or belting may be used. The general considerations for determining the size of dynamo unit will hold just the same as with the steam plant, and, indeed, the whole station arrangements will be similar, except that the turbine will replace the boiler and engine. It is unnecessary to point out the simplicity of such a power station, or to refer to the advantages of the utilisation of waste water power by electricity—they are self-evident. It is not surprising that magnificent transmission plants have sprung into existence during the past few years; the wonder is that the number of such plants is not tenfold greater.

The Dynamo.—The function of the dynamo is to convert mechanical into electrical energy, and the machine, if well made, accomplishes this end in a most satisfactory manner. The ratio of conversion of a good dynamo at full load varies between 90 and 94 per cent., and this high efficiency is maintained through a considerable range of output; at half load it is about 85 to 90 per cent., and at one quarter load will not fall below 75 per cent.; while running on open circuit the energy absorbed is only sufficient to overcome the mechanical friction. If the plant be divided into suitable units, it will always be possible to run at nearly the full output of the dynamo, and so secure a high working efficiency. In addition to the high-speed dynamo already referred to, there is a so-called slow-speed type, which is steadily gaining favour among certain engineers. It is of recent development, and is the outcome of a desire to couple dynamos directly to the engine shaft.

The output of a dynamo is roughly proportional to the length of the armature into the square of its diameter = say $l D^2$. Let the surface velocity be fixed. If D be large then l will be small, and *vice versâ*. In order to design a slow-speed dynamo it is necessary then to take a large diameter and a short length for the armature proportions. This type of machine is heavy and costly, in consequence of the large field-magnets, yokes, and extended beds, and increased cost of machining and labour; but these disadvantages are, in the eyes of some designers, more than counterbalanced by the decreased speed.

American practice favours dynamos running at from 800 to 1,000 revolutions per minute, coupled with belts to high-pressure engines making from 200 to 350 revolutions. Continental engineers are leaning to the slow-speed steam dynamos, and recently huge plants, with units of 500 H.P. and upwards, with triple expansion condensing engines, have been laid down for town lighting. English engineers are very much divided on the subject at present; but there certainly seems to be a tendency to use steam dynamos of about 100 unit capacity, running at from 175 to 250 revolutions per minute.

Viewing the question of the electrical power station from all sides, and laying particular stress on the high tension that will be required, it appears that the dynamo should be belt-driven, and therefore it will be permissible to use high-speed dynamos. A convenient size high-tension transmission dynamo for work in British mines is 50 or 100 H.P.; the speed may be from 450 to 600 revolutions per minute.

The Line.—The success of an installation will very largely depend on the care and forethought shown in the selection of the gauge of copper and the erection of the line. As the general conditions to be observed will be discussed hereafter *seriatim*, it need only be noted here that the energy wasted in the conductor may be made as small as desired, for the loss varies directly as the length and inversely as the area of cross-section. There are, of course, limits both to gauge and length of conductor; but these are determined as much by financial as by practical considerations. The essential conditions of a successful line are:—Firstly, a continuous metallic circuit between the dynamo and the motor; and, secondly, high insulation resistance, so that the current does not leak to earth; for defective insulation means not only a direct loss of power but may also entail a risk of fire.

The Motor.—A motor presents to the eye an appearance similar to that of a dynamo, though its function is the converse, viz., to convert electrical into mechanical energy; it is, in fact, a reversed dynamo, is governed by precisely the same

* All rights reserved.

Hosted by Google

laws, and its action is accompanied by similar phenomena; and, moreover, it is quite as efficient. The reversibility of the dynamo is said to have been discovered by an accident in the first place, though more probably it was the result of the steady and laborious study of early inventors. Be this as it may, the fact has been thoroughly recognised, and full advantage has been taken of the opportunities afforded by it.

The Driven Machines.—The machines to be driven need no special reference, but care must be taken to couple them to the motors in a suitable manner. High-speed machines may often be connected directly to the motor-shaft; or they may be coupled by gearing or belts; and countershafts, friction clutches, and other devices may be used. But whatever arrangement be adopted, care must be taken that the motor speed and current be approximately those designed by the makers. If either of these two points be neglected, the motor will not be working under the best conditions, and there will be a loss in efficiency.

The general idea involved in the expression an "electrical transmission plant" has now been explained, and the way is cleared for a more minute study of the subject.

(To be continued.)

VARIABLE GEAR FOR ELECTRIC TRACTION.

The importance of a variable gearing for starting electrical tramcars or trains has been repeatedly urged in these columns, but the application of motors has up to the present been in the hands of electricians rather than engineers, and while the former have been busy in finding uses to which electrical power may be applied, engineers have hardly been awakened to the enormous losses which take place when a motor is started under full load. The usual system of resistances is simply barbarous, but nine electricians out of ten seem to be satisfied with it. By the use of a variable gear, not only would the waste of current be prevented, but the motor might be considerably reduced in size. A number of complicated and very ingenious gears have been proposed in Papers read by Mr. Aldrich before the Franklin Institute of Philadelphia, but they were all very bulky, and for the most part required two armatures. There are many theoretical solutions to the problem, and hitherto the most practicable have been the use of several distinct motors coupled in parallel or in series. This has been carried out to an extreme by Mr. Holroyd Smith, who used four motors at Bradford.

A really mechanical and satisfactory design of a variable gear has recently been made by Mr. W. Worby Beaumont, and, although restricted at present to an alternative rather than a variable gear, it is evidently the invention of an engineer rather than of an electrician. Two forms of this gear are illustrated herewith.

In one of these, Fig. 1, is shown an arrangement of gearing, partly in section, for electric tramcars. In it A represents a motor shaft, and A^2 a car-axle arranged as for single-reduction gearing. On the motor-spindle is fixed a double-faced disc magnet, B, current being sent into either of the two energising coils through the conductors + + and the return conductor −, according to which side of the magnet it is desired to use. On either side of the double magnet are pinions, J and J^1, connected to the keepers H and H^1, the pinions running loose upon the shaft of the motor and gearing with the wheels K and K^1, the one or the other, as may be desired. In starting a car, current would be sent through the left-hand coil by the conductors + −, and a brush, E, resting upon one of the collector rings, D. The keeper, H, would thus be drawn to and held by the magnet, the frictional hold being increased by the use of the pole-pieces or rings G, with annular projections fitting into grooves in the armature H. The small pinion J will thus be clutched to the magnet, and thereby to the motor shaft, and the car-axle A^2, will be driven at a speed corresponding to the ratio subsisting between the diameter of the pinion J and the wheel K. This in the diagram is a ratio of 4 to 1. The car having been started, or having ascended a hill by this means at the slow speed (the motor running at full speed), may now be driven at the higher speed due to the larger pinion J^1 and smaller wheel K^1, by cutting the current out of the left-hand coil and sending it through the right-hand coil. The keeper H is thus allowed to run loose upon the motor-spindle and the keeper H^1 is fixed to it, and the car will now be driven at the higher speed. This, in the case shown, would be double the lower speed.

As there are several arguments in favour of direct driving of cars or locomotives by armatures on the driving-axles, an arrangement of gearing for this system has been designed, and is shown in Fig. 2, partly in section. In this case the maximum

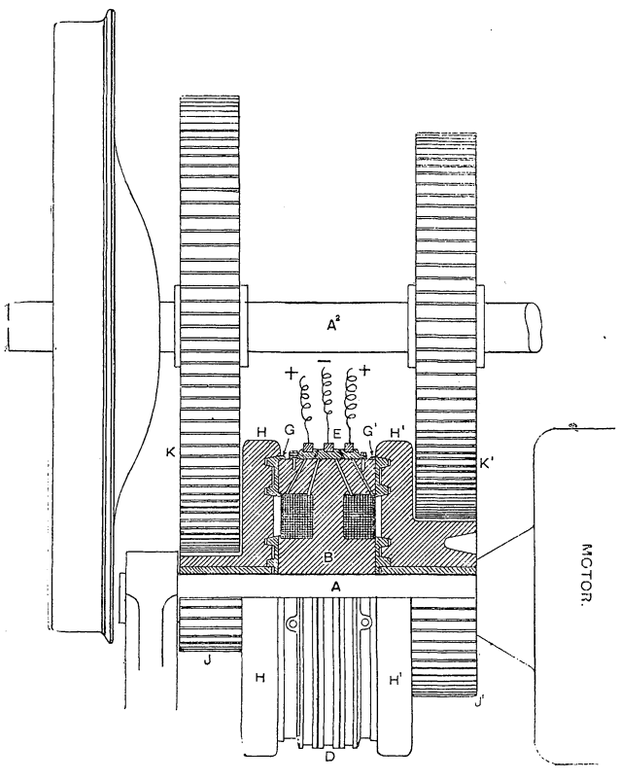

FIG. 1.—Electromagnetic Variable Speed Gear. Single Reduction Gearing.

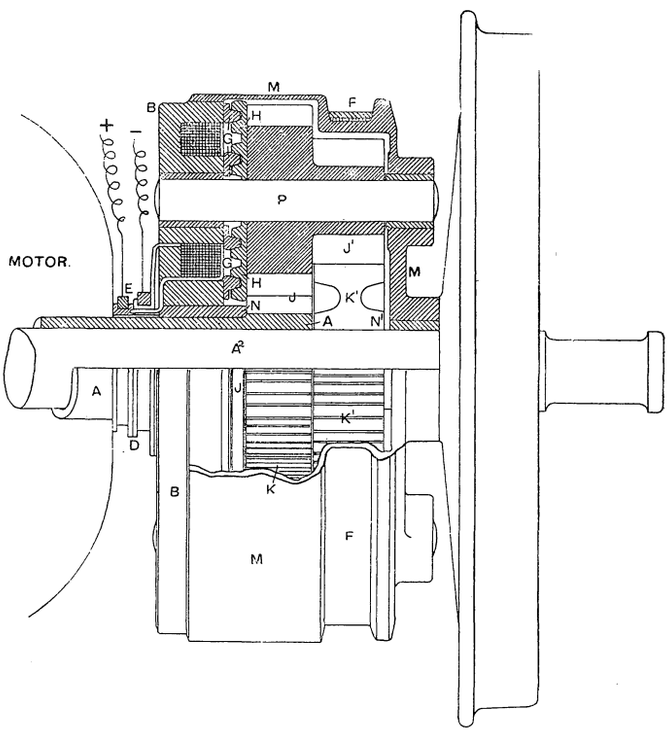

FIG. 2.—Electromagnetic Variable Speed Gear. Direct Driving.

Hosted by Google

speed is that of the motor, the shaft of which, A, is hollow and is mounted and runs upon the shaft to be driven, A^2, namely, the car or railway-axle. Upon the hollow motor-shaft A is fixed a pinion, J, gearing into an idle wheel, K, carrying, a pinion J^1, which gears into the wheel to be driven K^1 fixed to the shaft A^2. Fixed upon one face of the idle wheel K is an annularly-grooved disc-keeper H, into which the rings G, G on the pole-pieces of the disc-magnet B fit, forming a magnetic clutch. Two such clutches are employed in the arrangement shown. Current for energising the coils of these magnets is supplied through the conductors + − the brushes E and collector-rings D. By means of these magnetic clutches so formed, the idle wheel K and the connected pinion J^1 may be held fast, and when this is done the shaft A of the motor the whole of the gearing and containing case are locked together, so that the speed of the driven shaft becomes that of the driving shaft. For starting an electric car or locomotive current is cut out of the coils of the magnets B B, and is instead directed into a magnetic clutch-break, not shown in Fig. 2, except in so far as the clutch-break band is shown in section at F upon a part of the case M, which is made circular for the purpose. When this clutch break, F, is in action the case M is held fast, and the idle wheel K revolving with the spindle P drives the car axle A^2 at a speed which is proportional to the dimensions of the gearing. In the example shown, the motor shaft A would make two and a-half revolutions to one revolution of the car or locomotive-axle A^2. It will be seen that for ordinary running—that is to say, after starting and when not climbing a hill, the whole of the gearing was inactive.

Mr. Beaumont's invention is evidently capable of taking a number of different forms, and in his patents, we understand, a considerable number of these will be found. We do not know whether the following modification is one of them. Suppose in Fig. 1 that the pinion J^1 is fastened to the motor which runs upon a sleeve on the driving-axle. Let the magnetic clutch B, be keyed to the driving axle, and let A^2 be a counter-shaft, the arrangement may then be worked as the back gear of a lathe. For starting the car the left-hand annular magnetic coil would be energised, and the power would be transmitted from the pinion J^1 through the K^1 to K, and thence to J, the keeper, H, being clutched to B. On attaining speed, the right-hand coil would be energised, and the pinion, J^1, with the armature motor, would be clutched direct to B by means of the keeper, H^1. The only possible disadvantage that we can see in this arrangement would be that the gear-wheels, running idle, might cause some vibration and noise, but they would only be running at a differential speed, and, doing no work, should not cause any serious trouble.

In the above description we have not described the method of switching the current from one coil to another, but it is clear that the current, and, therefore, the clutching friction may be so controlled that passage from one gear to the other may be effected without shock. An electric clutch has a great advantage over the mechanical clutch in that the friction may be adjusted and controlled with perfect ease, without being dependent upon very minute differences of pressure produced by end-movement of parts upon a shaft. We hope before long to see Mr. Beaumont's invention actually put into practice.

THE DESIGN OF TRANSFORMERS AND CHOKING COILS.

BY JAMES WHITCHER.

If any apology is needed for touching upon this familiar theme, I put one forward in the belief that there is still much of mystery in it for some practical men, as well as for many of the new hands that are crowding with hasty enthusiasm into the trade. So that if perchance the subject demands their attention, and, as more often, with a call quickened with all the disconcerting urgency that commercial exigencies can devise, they are found wanting, or else must make a hasty painful gleaning along the thorny paths of empirics.

Generally the mathematical design of transformers and choking coils runs on common lines up to a certain point; and the fundamental formulæ of the one apply equally to the other, though there are usually very different conditions. To establish our first mathematical conceptions of a transformer we should regard it simply as a choking coil designed theoretically to choke off all current. Thus, if in simile we describe a choking coil as a magnetic sluice gate, a transformer would correspond to the condition of a sluice gate shut right down. The primary coil alone comes into these preliminary considerations, the secondary being only concerned therein in respect of the space it will occupy. And we would here remark it is well to dismiss once for all one's vague notions of mutual induction; the term is a mere catch phrase, a snare for the unwary. The truly logical method of treating the subject is to keep the two steps quite distinct—the production of an alternating magnetic field by the primary current, and the consequent production of an alternating E.M.F. of opposite phase in both the primary and secondary coils. The reaction of a secondary current upon the field, and through the field upon the primary current, maintaining equivalence of the ampere turns of each coil, can then be more readily seen and appreciated than if it is attempted to arrive at it by reasoning around mutual inductions without reference to the field.

The following symbols will be used :—

E = The maximum E.M.F. of electrical source or supply. The alternations will be assumed to be true harmonic variations; and therefore E will equal the nominal or virtual E.M.F. of supply in C.G.S. units multiplied by $\sqrt{2}$ or $-E = 10^8 \times \sqrt{2} \times$ nominal volts.

e = Any instantaneous value of the E.M.F. of supply : being a harmonic or sine variable $e = E \sin pt$.

B = Maximum induction in C.G.S. lines per square centimetre.

b = Any instantaneous value of the induction : it is also a sine variable and $b = B \sin (pt - 90)$.

n = Frequency or number of complete alternations per second.

I = Maximum current in primary supposing secondary absent or on open circuit: usually called exciting current, being that current which produces the alternating magnetic field :—in C.G.S. units. 10 amps. = 1 C.G.S. unit.

i = Any instantaneous value of the exciting current : it is a complex variable, and, paradoxical as it may seem, is a function of b, the induction it generates.

S = The number of primary turns. The word "turn" may mislead, as I have known it to do: it may be better defined as the number of times the conductor repeats itself upon the field, which includes the case of a straight conductor in relation to its adjacent field without regard of the remainder of the electric circuit.

A = The sectional area of the magnetic circuit in square centimetres.

l = The mean length of the magnetic circuit in cms.

μ = The permeability of the iron : it is an irregular dependent variable of b.

$p = 2\pi n$. A multiplier for converting linear measure of time into cyclic measure.

t = time in seconds measured from any moment e is passing through its *nil* value from negative to positive sign.

Now for a transformer, we have as our first consideration to design the primary as a choking coil which, while of very low resistance, shall permit only the smallest practicable current to pass through it when put across the supply mains; that is one in which this small current is sufficient to generate an alternating field of such strength that its reaction on the primary coils is to produce in them an opposing E.M.F. of self-induction equal to the E.M.F. of the supply. It should here be observed that in all inductive coils put on constant potential supply, the current through them will rise until the consequent E.M.F. of self-induction, together with the E.M.F. lost on resistance, are equal to the E.M.F. of supply; the object in transformers is to obtain this equality within a low range of current, and on the assumption that the ohmic E.M.F. is negligible.

Hosted by Google

Therefore, we must have the following relations :-

Induced E.M.F. varies directly as the rate of variation of the induction; and for a coil of S turns it is expressed thus in the language of the calculus which cannot easily be avoided :—

$$e_1 = \mathrm{S\,A}\,db/dt \quad . \quad . \quad . \quad . \quad (1)$$

therefore must $$-e = \mathrm{S\,A}\,db/dt \quad . \quad . \quad . \quad . \quad (2)$$

and $$-\mathrm{E}\sin pt = \mathrm{S\,A}\,db/dt \quad . \quad . \quad . \quad . \quad (3)$$

integrating $$\mathrm{E}\,cospt/p = \mathrm{S\,A}\,b \quad . \quad . \quad . \quad . \quad . \quad (4)$$

Now, b is a sine variable because e is a sine variable, but the variation is not co-phasal, as may be seen from equation (2); that is to say, e and b do not reach their maximums at the same time. For by the rules of maxima and minima b is at maximum when $db/dt = 0$; and as $db/dt = -e/\mathrm{A\,S}$, b is maximum when $e = 0$. Now $e = \mathrm{E}\sin pt$ is only $= 0$ when pt is 0deg. or any multiple of 180deg.; and since $b = \mathrm{B}\sin x$ there must be a difference of 90deg. between pt and x; and x must be behind pt or $= pt - 90$, since b is an effect of e. Therefore

$$\mathrm{E}\cos pt/p = \mathrm{S\,A\,B}\sin(pt - 90) \quad . \quad . \quad . \quad (5)$$

$$\mathrm{E} = \mathrm{S\,A\,B}p = 2\pi n\,\mathrm{S\,A\,B} \quad . \quad . \quad . \quad . \quad . \quad . \quad (6)$$

$$\mathrm{A\,S} = \mathrm{E}/2\pi n\,\mathrm{B} \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad (7)$$

$$= 0{\cdot}2251\ \mathrm{E_1}/\mathrm{B}n \text{ and} = 22510000\,\mathrm{E_2}/\mathrm{B}n \quad (8)$$

where $\mathrm{E_1}$ and $\mathrm{E_2}$ are the virtual E.M.F. in C.G.S. units and volts respectively.

This is a very important relation: given the voltage and frequency of the supply, and having determined on a suitable induction maximum, we have a simple numerical relation which must subsist between the cross sectional area of uniform field and the number of primary turns, altogether irrespective of the size or capacity of the transformer.

Having worked out the numerical value for the right side of the equation, changes may be rung on the possible values for A and S and likely ones chosen for trial.

The next process is to determine the exciting power or magnetomotive force necessary to produce the magnetic flux of maximum intensity B. In working this out we may find the number of turns fixed upon in the first place insufficient or otherwise unsuitable, and other values must be tried. Here the output of the apparatus comes in question. The size of wire for the coil is determined by the current to be carried at full load. Account must be taken of the drop of volts through the coil due to the $\mathrm{C^2R}$ loss; as the total length of wire is at first indefinite the full load density may be put at, say, 750 per square inch, and altered subsequently if desirable. The cross-sectional area of coil space can now be determined: in a transformer this should be doubled to provide for the secondary coil, which will have approximately the same area, having to convey an equal energy, and an allowance made for any outer taping or extra insulation.

Then, for a transformer or coil of the closed iron circuit type, the mean length of the magnetic circuit may be found from a diagram of the contour of the core, in the usual way by measuring along the centre lines of symmetry—a method near enough for practical purposes, but not entirely correct, as the induction is not in any form spread uniformly over the area as it assumes. An allowance must be made for joints; for lapping joints an addition of 10 to 30cms. to the length may be sufficient: butt joints are not advisable.

Magnetic flux is directly proportional to the magnetomotive force divided by the sum of magnetic resistances; that is

$$\mathrm{N} = \mathrm{A}\,b = \mathrm{M/R}. \quad . \quad . \quad . \quad . \quad . \quad (9)$$

Magnetic resistance varies directly as the length, and inversely as the area and permeability of the magnetic circuit. For a continuous circuit of iron, therefore,

$$\mathrm{R} = l/\mathrm{A}\,\mu \quad \text{and} \quad \mathrm{A}\,b = \mathrm{A\,M}\,\mu/l \text{ or } b = \mathrm{M}\,\mu/l \quad . \quad (10)$$

$$\mathrm{M} = 4\,\mu\,\mathrm{S}\,i \text{ and} \quad b = 4\,\pi\,\mathrm{S}\,i\,\mu/l \quad . \quad . \quad . \quad . \quad (11)$$

taking maximums $$\mathrm{B} = 4\,\pi\,\mathrm{S\,I}\,\mu/l \quad . \quad . \quad . \quad . \quad (12)$$

and $$\mathrm{I} = \mathrm{B}\,l/4\,\pi\,\mathrm{S}\,\mu \quad . \quad . \quad . \quad . \quad (13)$$

Here we have the maximum exciting current: if it exceeds, say, 10 per cent. of the effective amperes at full load, S should be increased till I comes within that percentage. In good practice the effective amperes of exciting current as measured by dynamometer is usually made from 2 to 5 per cent. of the full load effective amperes.

All the requisite dimensions can be satisfactorily determined from these simple relations: and the best relative weights of iron and copper found for the particular design. A few tentative experiments with the formulæ, substituting various values for the principal factors, will exhibit the influence these factors have over the result more clearly than much explanation.

The design of the secondary coil of transformer is a very simple matter. The required ratio of transformation gives the ratio of primary and secondary turns, unless there is appreciable magnetic leakage; with modern closed circuit transformers working at the low inductions usual, there is none to speak of. The respective sections of conductors should be to one another as the inverse of the same ratio; though sometimes the disposition of the two coils may cause the lengths and weights of wire in each coil to be disproportionate; so much so that in regard to the drop or ohmic loss it may be advisable to alter the relative sections. Generally the sum of the $\mathrm{C^2R}$ losses in both coils at full load should not exceed 2 per cent. of full load in watts; and commercial considerations show that it is folly to reduce it below 1 per cent.

The design of choking coils with closed magnetic circuits is practically identical with the preceding. Usually the conditions are that the coil shall generate in itself an opposing E.M.F. of given magnitude with the passage of a certain current. For instance, for working arc lamps on an alternating 100 volt circuit a coil is required to present a counter E.M.F. of about 50 volts with the lamp current of, say, 10 amperes flowing through it. The maximum value of these factors may be inserted for E and I in our formulæ, a value chosen for B and its dependant variable μ, and convenient dimensions found for A.S. and l. There is some uncertainty as to the maximum of the current, due to the irregular character of its curve, but practical calculations are usually sufficiently near if made on the assumption that the maximum is, say, 1·5 of the effective amperes.

It will probably be found that the amount of iron required is excessive; for the available magnetomotive force being large, b will need to be large, or S very small, in which latter case A becomes unwieldy. Making the induction larger causes waste and heating and noise, which should be avoided. But the iron may be reduced by any amount by the use of an air-gap in the magnetic circuit. A very narrow gap has a marked effect; and it is extremely useful for making the final regulation by a slight opening or closing of it.

The effect of the gap is exhibited in our formulae, thus—

$$\mathrm{N} = \mathrm{A}\,b = \mathrm{M/R} = \frac{\mathrm{M}}{\frac{l}{\mathrm{A}\,\mu} + \frac{l_1}{\mathrm{A_1}}} \quad . \quad . \quad . \quad . \quad (14)$$

where l_1 and $\mathrm{A_1}$ represent the length and area of the gap. This method only applies when l_1 is small. Presuming there is no polar enlargement, $\mathrm{A_1}$ may be taken as equal to A + a surrounding fringe of width equal to the length of gap as usual in dynamo design, or less accurately as equal to A. Then

$$b = \frac{\mathrm{M}}{\frac{l}{\mu} + l_1} = 4\,\pi\,\mathrm{S}\,i\left(\frac{\mu}{l + \mu l_1}\right) \quad . \quad . \quad . \quad . \quad (15)$$

Comparing this equation with that for closed circuits,

$$b = 4\,\pi\,\mathrm{S}\,i\,\mu/l \quad . \quad . \quad . \quad . \quad . \quad (11)$$

and remembering that the value of μ is numerically large compared with that of l: the great influence of an air gap can be seen. Here is a strong argument against the use of butt joints in transformers unless fitted in a perfect and therefore costly manner.

Choking coils, as well as being almost wasteless substitutes for resistances, have a further utility over dead resistance. Thus a resistance offers only what may be described as a linear regulation; that is to say, if the E.M.F. on it is altered in any ratio—for instance, doubled—the current through it is doubled too. But choking coils offer greater flexibility of design in this particular. If the working induction is chosen so that μ is near its summit value the regulation in one direc-

Hosted by Google

tion will approximate to that of a resistance: but by putting the induction at such a point that the permeability is on the rising slope of its curve, regulation of a sharper kind may be secured. In other words, the current is restricted to a shorter range than the volts; and if an induction be taken with the permeability on the downward slope this condition is reversed.

This property may prove of use in connection with apparatus that are liable to make sudden and disturbing demands for current on a constant potential supply; for example large arc lamps. Supposing it a 50 ampere lamp on 100 volt circuit; with resistance the current at starting will range up to about 100 amperes; and if at lower voltage the limit will be proportionately greater. With a coil designed with induction of 5,000 the range of current under some conditions may be kept under 65 amperes about. This can only be obtained with coils having complete magnetic circuit of iron; the presence of an air-gap masks the effect.

In an even more emphatic effect of this kind is required it might be obtained by making coil with an air-gap which opens and closes automatically with fall and rise of current. The magnetic condition of the core will generally yield a sufficient tractive force to do this against an opening spring the force of which can be readily regulated.

Thus much for the simple mathematical design of these important appliances. There is much to be said of the mechanical design of the same, also of the design of transformers for particular load factors or conditions of working, and of the whole question of the pre-estimation of losses; but it must be left for other occasions. Open circuit coils and transformers, and alternating current solenoids, are much more difficult of treatment than the simpler cases taken, yet they have some very important practical bearings.

The above must not be regarded as more than a plain statement of first principles put in practical form with as little mathematics as possible. More refined methods of designing transformers there are, involving less tentative work, but they require more mathematical gymnastics than some may like to venture on at first.

TEMPERATURE COEFFICIENT OF MERCURY.

BY KREICHGAUER AND JAEGER.

A series of very elaborate and careful researches on this point are among the latest work of the Reichsanstalt. The resistances of the copies of the mercury standard (about half a-dozen in number) have been measured in the most accurate manner possible, with results published in full in Wiedemann's *Annalen*.*

The authors of the article give as the formula for the alteration of resistance of the mercury in Jena glass tubes

$$r_t = r_o[1+0{\cdot}000875t+0{\cdot}00000125t^2],$$

and for the true alteration of specific resistance of the mercury

$$r_t = r_o\,[1+0{\cdot}0008827t+0\ 00000126t^2].$$

These values agree very well with those of Benoît and Guilleaume, principally on account of the identity of temperature scale used. The observations are between 0 deg. and 28 deg. Centigrade.

A NULL METHOD OF MEASURING SPECIFIC INDUCTIVE CAPACITY OF CONDUCTING LIQUIDS.†

BY F. HEERWAGEN.

The author's null method consists in the use of a differential electrometer, which is so constructed that two electrometer needles are fixed to a common axle and hang in quadrant pairs over one another.

The needles, case, and one pair of quadrants in each instrument are connected together, and to a certain point A of a circuit, while from two other points B and C in the same circuit wires are led to the remaining pair of quadrants in each instrument. When B and C are so chosen that there is no deflection of the needle-axle, the ratio of the sensibility of the two electrometers is inversely proportional to the ratio of the squares of the respective potential differences—that is, to the ratio of the squares of the resistances between AB and AC.

* No. 12. 1892. † Abstract from *Wied. Ann.*, No. 1, 1893.

If W_e / W_f be this ratio when air is the dielectric, and W_L/W_F be the ratio when the lower electrometer is filled with the liquid to be measured, then the specific inductive capacity of the liquid is

$$K=(W_L/W_F \,.\, W_f / W_e)^2,$$

alternating currents must, of course, be used.

The upper electrometer should be more sensitive than the one which is filled with the liquid.

The resistance of the suspension prevents the needles from being accurately at the same potential as the case—a fact to which the author calls particular attention. An equivalent resistance should be provided between A and the case and quadrants.

The author finds the value of the specific inductive capacity for pure water, after allowing for all corrections

$$K=79{\cdot}56 \text{ @ } 20{\cdot}75°C.$$

BOOKS, &c., RECEIVED.

SPECIAL NOTICE.

With an early issue of "THE ELECTRICIAN" will be published (Gratis to Subscribers) a fine Steel-Plate Portrait of the late Dr. WERNER VON SIEMENS.

STEEL-PLATE PORTRAITS

Of Willoughby Smith; W. H. Preece, F.R.S. (President of the Institution of Electrical Engineers); Michael Faraday; Sir John Pender, G.C.M.G., M.P.; Sir William Thomson, F.R.S. (Lord Kelvin); C. H. B. Patey, C. B.; Dr. John Hopkinson, F.R.S.; Dr. Oliver J. Lodge, F.R.S.; Prof. William Crookes, F.R.S.; Prof. von Helmholtz; Prof. W. E. Ayrton; Lord Rayleigh, F.R.S.; and Cyrus W. Field, have been issued as Supplements to "THE ELECTRICIAN."

A few Copies of these admirably-executed Steel Engravings can be supplied price 1s. each, post free on roller, 1s. 2d. Or framed in neat Black Pillar or Brown Ornamental Frames, price, 4s. 6d., carriage paid (U.K.)

ALTERNATOR AND DYNAMO TESTING.

The very interesting communication which has been made by Mr. MORDEY to the Institution of Electrical Engineers would have been accepted with less criticism, and would have led, perhaps, to a more useful discussion, if it had been put forward as an account of experiments to be performed with alternators. These experiments, being purely electrical, will, no doubt, contribute to the elucidation of the obscure phenomena which complicate the action of alternators. In one sense the author is perfectly right when he disclaims any intention of testing the mechanical features of the design; the only mistake is to call his method a test at all. Many interesting and valuable experiments have been made with steam-engines by Mr. DONKIN and others, but these are not called tests. The more is the title of the Paper to be regretted since the result which is obtained by these experi-

Hosted by Google

ments has a superficial resemblance to a true efficiency test. We do not for a moment desire to depreciate the importance of the study of the losses which occur in alternators, and welcome this ingenious and promising experimental method as one which will doubtless conduce to improvements in electrical design. It is hardly fair to criticise remarks which may be let drop in the course of a reply to a discussion, but if it was really meant that no test of dynamo shafts is necessary because the maker knows quite well what size of shafts to put in for various powers, and that he can ignore bearings because he is quite satisfied about his own, why not extend the principle and send out the dynamos without any "test" at all? Some caustic remark, which was not caught by the reporter, was made about "people who have had no experience of running machinery." It was, perhaps, of no great importance, but the attitude thus adopted is just sufficient to widen the distinction between electricians and electrical engineers. If there need be any choice of one of two tests, we would rather have a common-sense mechanical test, say, a full load run for a few hours, and in the case of an alternator a light run also, and take the electrical efficiency on the maker's word.

The rise of temperature after a run is an excellent but too lightly valued indication of the efficiency of a dynamo or alternator. Disparaging remarks about dynamos are sometimes made by rival makers or by disappointed users, and very low efficiencies are attributed to large machines in forgetfulness of the fact that all losses must appear as heat. We have been assured that a certain 20-kilowatt machine had an efficiency of only 65 or 70 per cent, but, nevertheless, it ran fairly cool at full load, while, according to our informant, some 10 kilowatts must have been disappearing, and could only have disappeared as heat. If a machine heats badly its efficiency must be low, whatever the wattmeters and tests may say. The converse will not always hold, for heating may be dispersed by careful ventilation. Losses may be roughly localised by examination of the heating, but Mr. Mordey's method will, no doubt, prove exceedingly useful in measuring and identifying them. His contention that the losses in side pull on the bearings is not serious, is supported by the fact that well-designed and well-kept bearings run cool enough. Absence of heat is quite sufficient proof of absence of loss, whether by friction, by current, or by hysteresis. Belt losses, however, cannot even be guessed at in this way, since so great facilities are given for cooling by passage through the air; similarly, the heat of an armature, as is well known, soaks out after stopping, the surface having been kept cool while it was in motion. While preferring a full load run to a scientific test on the "internal circulation" principle, it is obvious that makers may not have the means of running large dynamos at their works. Here Dr. Hopkinson's original method is invaluable, for they must be able engineers or good salesmen who have not left on their hands one or two machines with which such an "external circulation" can be carried out. No sooner was the account of Dr. Hopkinson's method published than several engineers at once put into practice the purely electrical method soon afterwards suggested by Lord Rayleigh. A firm of dynamo makers, a few years ago, received an order for some large machines under the stringent and then new specification of the Admiralty. A four or five-hour well-loaded run was necessary, but although they had a good engine devoted to testing, the boiler was quite unequal to the task of running both the dynamo and the factory. Runs at low speed and at under-excitation were tried but were not relied on, but a Sunday or all-night test was avoided by shutting down the factory engine, and running the shafting from the dynamo generally used for lighting the shops, but run with part of the waste power as a motor.

Mr. Mordey's directions for running alternators in parallel will no doubt be useful to those who desire so to use his machines, but we are not so sanguine as Prof. Ayrton that anyone can now perform the operation with any alternator. It is easy enough to give recipes, as for example, "To catch hares, stand behind a tree and make a noise like a turnip," but it is not always easy to put them in practice. Having caught your hare, or having got your alternators into step, how are they to be kept equally loaded? Mr. Swinburne has discussed this at considerable length, and while his directions have never been shown to be misleading, other people seem to be coming round to his idea, under the impression, apparently, that it is their own, namely, that only a single governor (other than run-away governors) should be provided in a central station in which alternators are run in parallel.

SPARKING AT COMMUTATORS.

BY F. M. WEYMOUTH.

(*Concluded from page 543.*)

We may now take note of some general effects and conclusions. In the first instance, it is to be observed that the effect of the short-circuit currents is to divert the flow of the main current from its natural path or paths, which it would take according to Ohm's law. The effect of this is thus seen to be most disastrous, where, as in the cases of the brushes at A and B, these are moved too far back. For here the whole of the main current is being made to pass through the lug of the receding segments. When the brushes are too far forward, on the other hand, there is only light back-sparking of short-circuit current, and the whole of the main current is made to flow through the heels of the brushes.

Another point that may engage our attention, concerns the position of the plane of commutation in relation to the variously misplaced brushes. On an earlier page we stated that this followed the brushes, but *but with some degree of elasticity.* It will be observed that this plane, lettered *C n P* in the diagrams, is shown in Fig. 15 (lettered *C n* only) with each pair of brushes. At brushes A and B it runs through the points, while at C and D it passes through just within the heels of the brushes.

If we thus examine Figs. 16 and 18, showing brushes A and B, we shall observe that on the recession of segment *r*, and the breaking of the assumed current of 650 amperes, a *sudden* reversal is *forced* to take placed in the coil *b*, by its being thrown completely among the series *c* in the former, and *d* in the latter. The coils *b*, in fact, in both these cases are thus suddenly commutated at that exact instant. Hence the plane they are then in is the plane of commutation for those positions of the brushes; and if the plane of the coil runs through the points of the brushes, as shown in the diagrams, so also will the plane of commutation.

To turn now, however, to Figs. 17 and 19, showing brushes C and D, we find here that it is not the forward coils *b* that are first reversed, but the hindmost coils, *f*; and in the diagrams this reversal is assumed to have taken place, and *b* and *f* are both prepared to be thrown among the other series of coils they are approaching, excepting in so far as they are carrying a current which is too great. It will be noted that directly on the two segments *t* making contact with the heels of the brushes, the coils *f* will have become short-circuited. But up to that instant they have had within them the current direction and polarity of the coils *behind* the brushes. This has now to be reversed. But it has to be further remarked, that the E.M.F. in the coils between *f* and the *N P* plane, has already been weakened by the fact that, with brush C, there has been a counter *c* E.M.F. taking effect in them, due to their being on

Hosted by Google

the c side of that plane; and a counter d E.M.F. acting similarly with brush D. The reversal is thus so far prepared for; and it is now accomplished by the electromotive force of coil f. As we have already pointed out, this reversal is not here necessarily sudden, for it takes place after a *making* of contact between the brush heels and segments t, and not at a break. Hence the exact position of the plane of commutation will be that plane occupied by the coils f when they have an infinitesimally small amount of the reverse current from b commencing to run in them—with which, it will be borne in mind, the current in the series of coils forward of the brushes, is assimilated. And this position, with the plane of the leading short-circuited coil cutting through the points of the brushes, we have assumed to be just forward of the heels, as indicated by the lines $C\,n\,P$ in the diagrams of the brushes C and D under discussion, and lines $C\,n$ in Fig. 15.

We have alluded to the fact that in the cases of the brushes at C and D, the currents broken at the recession of the segments r are merely short circuit currents. A question might arise as to exactly in what manner the self-induction of these short circuits takes effect, so as to produce sparking. Inspection, however, will show that this is due to the sudden reduction at the moment of recesion, of the 500 amperes in the coils b, to the normal 200 of the series of coils among which they are being thrown. For by the operation of Lenz's law, already dwelt on, so sudden a reduction will be resisted, in like manner, though not to the same degree, as a sudden reversal. Hence at the recession of r, a momentary very high E.M.F. will accumulate at the point of the brush, causing a discharge of disruptive sparks into r, followed by arcs, in the case of brush C; while the discharge will be from the segment r to the brush, in the position D. Both being contrary in direction to the main current, there is thus formed what has been termed back-sparking.

It is at this juncture that we may allude to the comparative absence of sparking that attends the use of carbon brushes, to which reference was made at the outset of these remarks. There was some correspondence in *The Electrician* for July 15th of last year, on the subject of carbon brushes, in which this peculiar feature was mentioned. Some hints were then also thrown out as to the causes; while a full explanation appeared wanting. We would thus now venture to take this point into consideration, allowing it to fall within the general line of our argument.

With carbon brushes there are two causes in particular that tend to prevent sparking. Of these, the first is the higher resistance of the substance as compared with metal: while the second is the resistance of the *contact* between the brush and the segments of the commutator. It is the latter which we shall thus endeavour to show is by far the more important in accounting for the absence of sparking; though the former has also its effects.

Now, when carbon is used in any shape to form part of an electrical circuit, it is an understood thing that great care is always necessary in securing a good contact between it and any metal connection. Thus, in the case of carbons for a cell, we find the upper ends carefully encased in lead, and so a large surface of the actual carbon put in contact with that metal, to which latter terminals may be attached. Or again, as with the brushes now under discussion, it is considered distinctly advisable to thoroughly copper-plate the outer ends that go into the brush holders, and not merely the ends but a great part of the whole brush. The conclusion is thus negatively deducible, though indeed generally recognised, that the contact between carbon and metal, even when the contact surfaces are as bright and smooth as they can become, is yet not nearly so efficient for the passage of current as the contact between two bright metal surfaces.

Figs. 20 and 21 herewith illustrate the top of a commutator, as in previous diagrams, rotating in direction indicated by curved arrows. The hatched portions represent the contact surface of a carbon brush, shown in a different position in each. In Fig. 20 the brush is half on each segment, r and s. Let us now suppose the brush to be some way behind the neutral plane, like the brushes A and B, in immediately preceding diagrams, where with metal brushes there would be heavy sparking. Then, comparing Fig. 20 with Fig. 16, we know that the whole current of the armature, as well as the greater part of the short-circuit currents, are reaching the brush through lug g and segment r. It will thus be observed that this total of current is dependent for its entry into the brush on the contact surface $w\,x\,y\,z$, which is only, as shown, about half the total surface available. We may now note the effect of the gradual alteration to the conditions depicted in Fig. 21. The contact surface $w\,x\,y\,z$

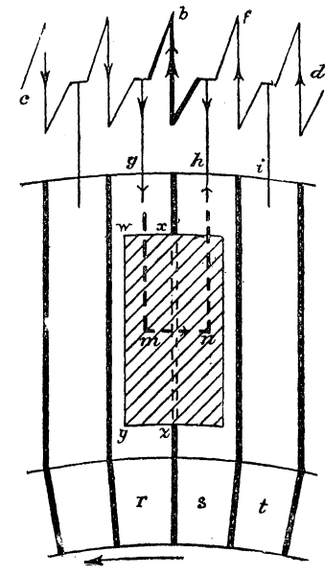

FIG. 20.—Carbon Brush. Short-Circuited Coil not reversed.

has become much contracted; and during contraction has become less and less able to let all the current pass. Hence the current, by the *resistance* of this decreasing contact surface has been *forced* to go through the coil or section of winding b and lug h, and so reach the brush. Hence by the time the recession of segment r actually takes place, the advance coil b has been commutated, and its polarity reversed, and it is carrying nearly or quite all the c current; and nearly the whole current

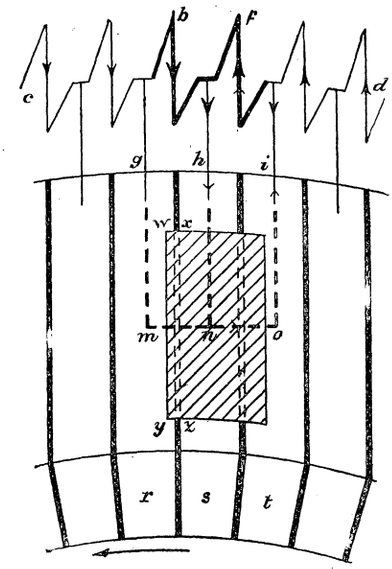

FIG. 21.—Carbon Brush. Reversal of Short-Circuited Coil prior to recession, owing to Resistance of Contracted Contact.

of the armature is entering by the lug h. Thus there is little or no current to break at the recession, or any self-induction effect to be incurred. Consequently there is little or no sparking.

It is found in practice that the forward edge of the brush $w\,y$ sometimes gets very hot, though there are no sparks. This is thus accounted for by the resistance of the contracted contact surface, which naturally becomes heated. Such an effect in the light of the above argument would thus point to

Hosted by Google

the fact that the brush would then be too far behind the proper neutral plane; as otherwise there would not be so much current endeavouring to pass through this small contact surface up to the moment of recession.

The short-circuit currents, however, have to be borne in mind. It will be remembered that when the brushes are *ahead* of the neutral plane, as at C and D, Figs. 15, 17, and 19, we showed that the sparking was due entirely to the breaking of short-circuit currents. Now we have pointed out that though under some circumstances such short-circuit currents may be large, they are yet impelled by but *small* electromotive forces, and they are large simply from want of resistance. It is palpable, that if such a current be due to a very small E.M.F., a very small resistance will reduce it to a negligible amount. Hence, by the comparatively great resistance of the contact, with the additional resistance of the carbon forming part of the short circuits on the line *m n o*, the short-circuit currents will be practically eliminated. Consequently, as there will be no current to break at the recession of the segment *r*, in these cases also, there will be no sparking.

OSCILLOGRAPHS FOR THE INVESTIGATION OF SLOW ELECTRIC OSCILLATIONS.*

BY A. BLONDEL.

The object of this communication is to describe some new galvanometric apparatus or *oscillographs* allowing one to determine by direct observation, and with sufficient accuracy, the periodic curves of alternating currents. It is only necessary to devise an instrument, the moving parts of which oscillate according to the law of variation of the current which traverses it. When this is done we can by means of well-known optical arrangements transform the oscillatory movement into a periodic curve and register it photographically. The problem is not new, and several instruments have been devised to solve it, such as the d'Arsonval galvanometer, the use of which was suggested both by M. d'Arsonval himself and by Prof. Éric Gérard; the mirror galvanometer, proposed by M. Colley; and the telephone, as proposed by Elihu Thomson, Fröhlich, and others. None of these instruments, however, have fulfilled the conditions imposed, which are five in number, the two first being of general application, and the three last being peculiar to the problem under consideration.

1. The instrument should have a natural period of oscillation very short when compared with that of the electric oscillations. In the case of ordinary alternating currents particularly, which have a frequency of between 40 and 100 periods per second, the galvanometer should vibrate with a frequency *at least* twenty times greater, *i.e.*, more than 1,000 to 2,000 complete periods per second.
2. The damping should be brought to as low a figure as possible, and as near as possible to the critical degree of dead-beatness, whenever the electrical oscillations are not quite continuous.
3. The self-induction should be sufficiently small not to affect the law of variation of the current measured.
4. Hysteresis and Foucault currents should be negligible.
5. The sensitiveness should be sufficient. This condition is the most onerous of all, and involves exceedingly small moving parts.

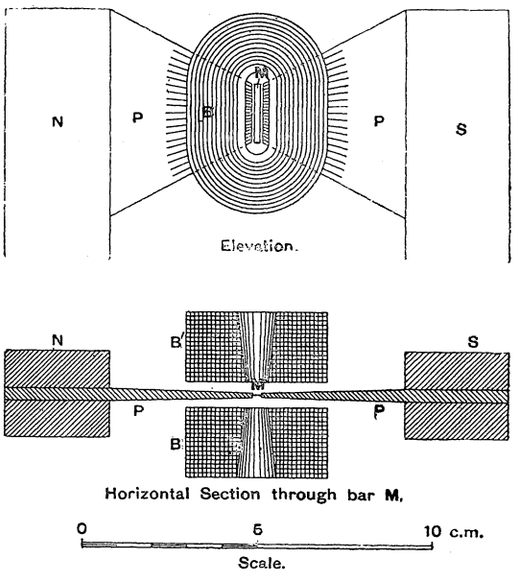
I examined three types of vibrators satisfying the first four conditions, but only the last was sufficiently sensitive.

Movable Coil Pattern.—The coil, similar to that of a siphon recorder, but carried by a spring or an elastic bifilar, must have dimensions much smaller than those realised up to the present, that is to say, the coil must be only a few millimetres in size. We can, it is true—and this is in some respects the best solution—suppress the coil, and only retain the bifilar traversed by the current to be examined, and carrying a mirror at its middle. The bifilar should be placed between the poles of an electro-magnet as elongated and as close together as possible. The instrument has practically no self-induction.

Vibrating Diaphragm Pattern.—This is a kind of telephone, improved in view of this special purpose by the employment of an independent magnetic field perpendicular to that produced by the current under examination. Between the poles of a horse-shoe magnet or electro-magnet a vertical diaphragm is arranged; this is as small as possible, and is recessed into one pole piece, and is free as regards the other. On either side of the diaphragm are placed two coreless coils, traversed by the current under examination.

Movable Bar Pattern.—This is quite naturally evolved from the preceding pattern, to which it is superior, owing to the smaller dimensions and smaller moment of inertia which it enables us to give to the vibrating part. Between the poles N, S (*see* Figure) of the magnet or electromagnet are placed two sheets, P, P, acting as pole pieces, and preferably cut V-shape to increase the field between their tips. A three or four millimetre gap is left, into which is inserted a little bar of soft iron M, two or three millimetres broad, and slightly thinner than the tips of the pole pieces (one to two millimetres). To enable this little bar to move under the influence of the two coils B, B, arranged on either side of the pole-pieces and traversed by the current under examination, without jamming against the poles, it is maintained in the required position either by two needles penetrating into very minute holes at the top and bottom of the little bar or by means of a spring or a specially shaped elastic bifilar to which it is soldered.

Without a spring the directing couple due to the magnetic field alone produces more than a thousand vibrations a second, and without the flat shape of the pole-pieces, which gives rise to considerable magnetic leakage, the figure obtained can be made much higher. With bifilar suspension or a spring it is easy to reach two or three thousand vibrations with sufficient sensitiveness, in many cases, for direction observation. The sensitiveness may be still further augmented by means of a microscope with a magnifying power of 10 to 20 diameters.



Diagrammatic Sketch of Oscillograph (half actual size).

The deflection being, all things being equal, proportional to the product $G I l P^2$, where I is intensity of magnetisation, l the width of the bar, P^2 its natural period of oscillation, G the "coefficient of action" of the coils, we see it is convenient to employ a very soft, very narrow, and very saturated piece of iron.

Owing to the shape of the pole-pieces, P, P, and of the magnetic circuit, and to the presence of a few horizontal saw-cuts along the plates and, if necessary, along the movable bar, hysteresis and Foucault currents are rendered quite negligible. Self-induction need only be feared if one employs the oscillograph as a voltmeter and uses fine wire coils; but, as a rule, it is possible to reduce the lag caused by self-induction to a small amount by the addition of a tolerably large dead resistance.

The chief difficulty I met with was in connection with damping, which I investigated by means of a photographic record of the vibrations on a revolving drum. At these high frequencies electro-magnetic damping becomes insufficient, for the damping necessary at the critical degree of dead-beatness is proportional to this frequency, and we are obliged to have recourse

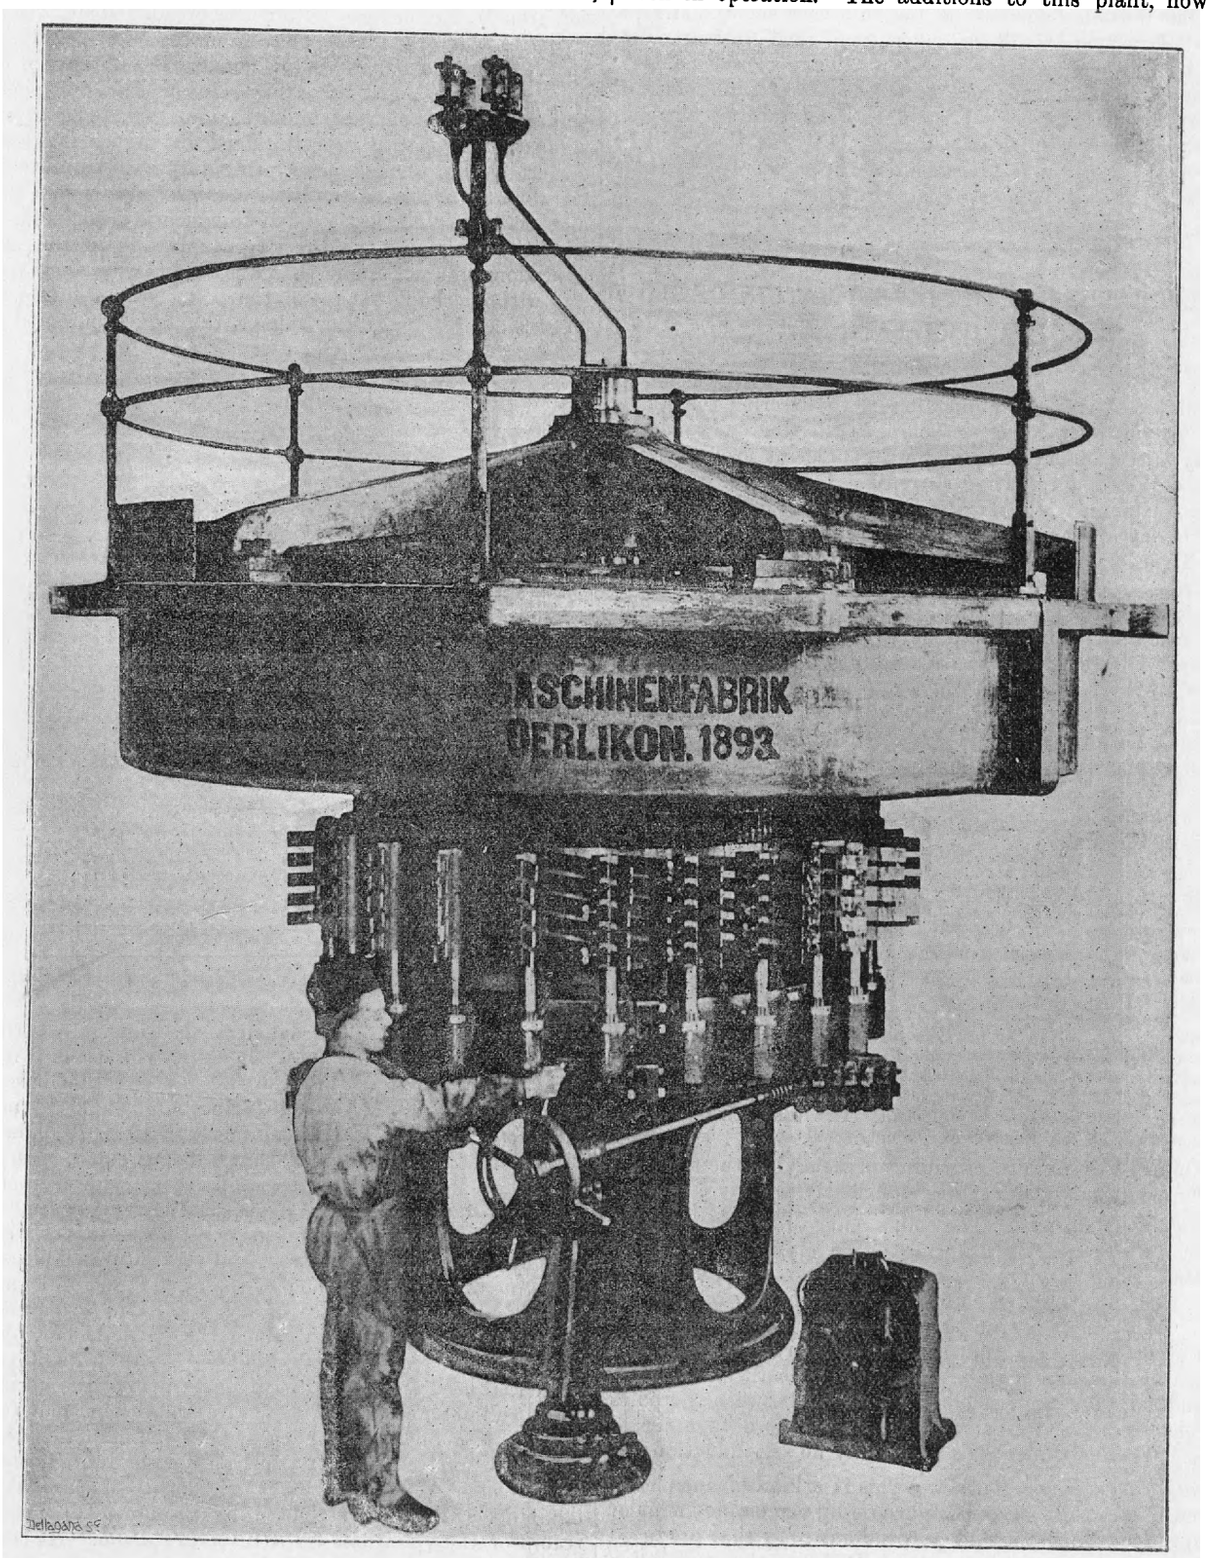
* *Comptes Rendus*, Vol. CXVI., No. 10, March 6, 1893, p. 502.

Hosted by Google

to mechanical means. I have passed over, for the time being, damping by aid of india-rubber dampers, because it is difficult to analyse and control them, and I had recourse to liquids of increasing viscocity—water, glycerine, resinous balsams, &c., which were introduced into a little closed ebonite box provided with a window and surrounding the ends of the pole-pieces and movable bar. Amongst the liquids tried, only the resinous balsams, especially the syrupy Canadian balsam, enabled me to attain the required degree of dead-beatness. I hope to be able to make known very shortly the results attained by means of this instrument when investigating certain particular cases of alternating currents.

OERLIKON 7,500-AMPERE 55-VOLT DYNAMO FOR ELECTROMETALLURGY.

One of the most prominent electrical plants in existence is that of the Aluminium-Industrie-Actien-Gesellschaft Neuhausen, of Neuhausen, Switzerland, which utilise water-powers of the celebrated falls of the Rhine. Up to the present, four dynamos of 150-H.P. each, one of 300-H.P., and two of 600-H.P. have been in operation. The additions to this plant, now nearly completed, comprise four new generators, designed to give 7,500 amperes at 55 volts pressure, and to run at 150 revolutions per



Hosted by Google

minute. There will then be six dynamos of 600-H.P. and one of 300-H.P. in one room, representing an aggregate capacity of 3,900-H.P.

The work is continuous. The huge commutators and the sets of 120 brushes per machine must, and do, work absolutely without sparking. There is but one man in charge of three or four of these dynamos. The throttle of the turbines and the brushes of the respective dynamos are handled from the same point.

The accompanying illustration is the reproduction of a photograph taken in the erecting-shop of the Maschinenfabrik Oerlikon, near Zürich. It represents a dynamo of over 400 kilowatts directly coupled with the turbine shaft. The star-like bracket on top of the magnet frame contains the top bearing of the dynamo shaft; the magnet has 24 radial inward pole-pieces, the whole being of cast iron, and supported by heavy iron structures, not shown in the picture. The dynamo shaft carries the armature and the commutator, a total weight of revolving masses of about 12 tons. The 120 brushes can be moved within certain limits by means of a hand-wheel. The magnetic proportions are such that there is but very little shifting of the brushes at varying loads. The machines are shunt-wound and self-exciting. To give some idea of the size of the dynamo, a medium-sized man and a small continuous-current Oerlikon 2½-unit dynamo has been photographed with the large machine.

The turbines are by Escher, Wyss, and Co., of Zürich. They are provided with a device to hydraulically counterbalance the weight of the revolving parts, and to thus relieve the bottom bearing of the vertical shafts. The buildings and the tunnel to carry the water, have been carried out by Messrs. Locher and Co., of Zürich.

RECENT TESTS OF FERRANTI METERS.

Some interesting particulars of the test of two disputed meters have been sent to us by Messrs. S. Z. de Ferranti, Limited. The test was carried out on the following understanding, that if the calibration of the two meters, which had been working independently in a London shop, agreed within 2½ per cent. either way, the check meter to be supplied by Messrs. Ferranti, the amount registered was to be paid for in full. The makers supplied a Ferranti meter calibrated between currents of from 10 to 60 amperes, and declared its constant. After the test this meter was sent to Faraday House Standardising Institution, who calibrated it. By Messrs. Ferranti's calibration the meters over-registered 1·4 per cent., by the Standardising calibration they had under-registered 0·83 per cent. This difference is due to the variation in the standard, no doubt.

A full description of this type of meter was published in *The Electrician*, Vol. XXVIII., p. 537. The following is a general description:—

All meters up to and including the 300 ampere size start registering with an 8 c.p. lamp. There is no shunt-current wasted in the meter, the initial friction being compensated for by steel pole-pieces, the remaining iron parts of the meter being made of soft iron. The form of field is a closed magnetic circuit, the gap between the pole-pieces, in which is the mercury chamber, being surrounded by a steel ring which acts, as it were, as a keeper. The maximum working current which passes through the meter magnetises the steel pole-pieces to the required degree for compensating the meter on starting. The rotating parts of the meter, which are exceedingly light, are of a metal which is non-magnetic, and is not attacked by mercury. The whole of the revolving part is entirely submerged beneath the mercury, and the spindle which conveys the motion of the mercury to the train of wheels, is made of very small diameter so as to avoid, as far as possible, the surface tension of the mercury, this being found to be one of the initial difficulties in 1883.

The curve of one of the meters taken when working with a smooth insulated surface on either pole-piece is one which is not proportional to the current passed. The meter tends to run faster as the current increases. This is ingeniously corrected by radial roughening of the two insulated surfaces, and by this means it is easy to get the curve of the meter straight. The dial of the meter is now made so that a ratio wheel can be put in, in order that, as soon as the meter has been calibrated and the curve found to be straight, the meter can be made to read direct in Board of Trade units on the dial at any declared voltage without alteration to the meter internally. The speed of rotation of the meter is kept down to about 250 revolutions maximum.

The two disputed meters, Nos. 386 and 404, had been at work from June 25, 1892, until January 23, 1893, and had registered respectively 968 and 2,440 units.

Test of Two 100-ampere Ferranti Meters *at the generating station of Supply Company, reading in B.T.U. at 110 volts.*

Time in hours.	Approximate current by ammeter.	Meter. 386	Meter. 404	By Ferranti Company calibration.	By Stand. Inst. calibration.
1·0	40-60	5·0	5·0	4·93	5·16
1·5	40-60	7·4	7·4	7·34	7·59
1·75	40-60	7·9	8·0	7·83	8·07
1·33	25-30	4·1	4·0	4·0	4·03
	Total	12·0	12·0	11·83	12·3

Meter (check meter). 1425

All the above meters 100 ampere size. This showed the two meters to be:—By Ferranti Company's calibration, 1·4 per cent. high; by the Standardising Institution calibration, 0·83 per cent. low.

PARTICULARS OF TEST.

Present: Engineers of Supply Company, consulting engineer of customers, and Messrs. Ferranti's representative.

Ferranti meter, 1,425; constant declared as below:—

$\frac{3{\cdot}05 \times 60}{18{\cdot}300}$ revs. per ampere per hour.

$\frac{10}{1{,}830{\cdot}00}$ revs. with 10 amperes per hour, per B.T.U. at 100 volts,

$\frac{1{,}830 \times 100}{110}$ = 1,663·0 revs. per B.T.U. at 110 volts.

Constant as declared by the Standardising Institution:—

22 amperes, 1,652·0 } at 110 volts. See copy below.
43 amperes, 1,608·0 }

CERTIFICATE OF EXAMINATION *issued by the Electrical Standardising, Testing, and Training Institution, Faraday House.*

ON TESTING AND WORKING ALTERNATORS.

The following is an abstract of the discussion on Mr. Mordey's Paper which took place on February 23rd and March 9th, at the Institution of Electrical Engineers. Speakers whose remarks are prefaced by an asterisk have returned their proofs revised.

*Mr. MILLER, introduced by Prof. Ayrton, said that some months ago Mr. Mordey described to Prof. Ayrton the ingenious method of measuring the output and efficiency of an alternator which had formed the subject of the Paper just read. This method appeared at first sight to be only practicable when the armature was stationary. But it subsequently occurred to Prof. Ayrton and Dr. Sumpner that the principle of using one-half of an alternator as a generator and the other half as a motor was quite as applicable to a rotating armature and many-poled field. If the stationary field magnet were electrically divided into two parts and the connections of one-half reversed, then, without any other change in the rotating armature, one-half of the machine acted as an alternating motor while the other remained a generator. Messrs. Fleming, Nicholson, and the speaker had carried out a series of experiments on the 12 H.P. Ferranti alternator at the City and Guilds Central Institution, and the results confirmed the idea that this method of testing an alternator with a rotating armature could be practically employed. The field magnet coils of the Ferranti dynamo were connected in parallel so that the current passed round the upper and lower coils in opposite directions. The alternator was driven direct by a continuous-current motor. Throughout the experiment the currents in the two halves of the field of the alternator were so adjusted as to produce sufficient electromotive force in the armature (which was short-circuited by an ammeter) to send 20 amperes through the armature. The alternator was run at different-measured speeds and the power required to drive the motor measured. Subtracting the power wasted in heating the two armatures, they obtained the power expended on eddy-currents and friction. The power wasted in the motor was then separately determined by ascertaining the power required to drive the motor at the same speed when its spindle had been uncoupled from that of the alternator. So that finally they had the power wasted in the Ferranti alternator. Having obtained this it was then quite easy to calculate the efficiency at different speeds by aid of the characteristic curves.

*Prof. AYRTON said it would be seen that that method of testing an alternator with a rotating armature by dividing the field into two parts was equally applicable to direct-current multipolar machines. Such a machine could be tested at once by simply disconnecting one-half of the field, and joining it up electrically the wrong way, so to say, to the other half. It was not necessary, as Mr. Mordey suggested, to have two commutators on the armature. Of course there was one point about all the methods, one objection, which did not apply to the original method suggested by Dr. Hopkinson some years ago In Dr. Hopkinson's method there were two distinct direct-current machines with their shafts coupled together, one working as a motor and one as a dynamo, and the power that each machine was developing was actually transmitted through the shaft. Now it was to be observed in the interesting method which Mr. Mordey had described, and the extension of it described by Mr. Miller, that the stress on the shaft was not tested at all, and it might be that the shaft would be weak or the bearings might heat when the shaft was required to transmit 100 H.P., which would not come out at all in the method of testing described. It was quite clear that if one had not an engine giving more than 10 H.P. one could not in any way transmit 100 H.P. through the shaft. It might be objected that the method he had spoken of resulted in a distortion of the field, and the result would not truly represent what would happen if there were no distortion. That was true to some extent, and it was also true of Mr. Mordey's method. With a multipolar field that was not a very serious matter. With two poles, no doubt, it would be a serious matter ; the whole of the lines of force would be distorted. What Mr. Mordey had said about the currents in parallel coils of an armature flowing back through the coils was very interesting, and the students had noticed it in a very marked way in connection with a transformer where the secondary consisted of two coils in parallel. Prof. Perry pointed out some time ago that if one portion of a transformer, whether the primary or the secondary, consisted of two coils in parallel, then there was the liability to have the currents circling round that coil with the two halves in opposite directions if the numbers of convolutions were not exactly the same, but he had not seen, apparently, that the difference in magnetic leakage alone would cause circling of the current in two parallel coils, whether of the primary or secondary, and such circling to a surprising amount had been noticed with such a transformer at the Central Institution. They had heard that evening an extremely interesting Paper, interesting from a variety of reasons—interesting, first, because it proposed a new method of testing alternators, which enabled the alternator to be tested with a very small amount of power, and especially interesting, he thought, from the last part, which gave rules for the parallel working of alternators. It had been urged by those who were in favour of direct-current working that it was impossible to work alternators successfully in parallel, but with the instructions which Mr. Mordey had drawn out so fully, it would seem that that difficulty was got over, and that it would not, therefore, any longer be an argument against alternators that they could not be worked in parallel.

*Prof. SILVANUS P. THOMPSON said they had once more to congratulate Mr. Mordey on a thoroughly happy Paper. There were two or three points in the Paper that perhaps called for a little more than passing comment. For example, the very curious and interesting diagram of the current required in the field of the motor at different stages of excitation brought home to them, in a way that nothing else would do, the meaning of Dr. Hopkinson's prediction, that they could run a motor with a higher electromotive force than the generator that was feeding it. That was a matter of practical importance too, because it was obvious that motors ought always to be so run, that the current running up and down the mains should be a minimum. There were one or two little points of criticism which he hoped Mr. Mordey would not object to his raising. When Mr. Mordey divided the armature into two parts, as in Fig. 1, or any of the others, and ran the machine thus, that surely was not quite exactly the equivalent of running a generator and a motor, because the generator and the motor were not rigidly coupled together so that the volts were necessarily in entire opposition of phase, and if there was any self-induction in the circuit in between, if there was any capacity in the circuit in between, then there would be a difference of phase between the two machines, that was to say, they would not be exactly in opposition of phase as they were in the motor-coils and the generator-coils in the divided machines. Again, Mr. Mordey made the assumption that the efficiency of a machine as a motor was the same as when used as a generator. Well, that depended to some extent on the conditions of the circuit. Again, Mr. Mordey said "Running at full current and small power may also be done by using simple choking-coils for the external circuit, but this introduces disturbing influences which make it of very little use." Those were exactly the disturbing influences that did come in, in running. He would make the same criticism as he should have done on Dr. Fleming's paper if he had had the opportunity. It was a very valuable paper, but the conditions under which the tests were made, excellent as they were for giving something like a distinct view of the subject, were really not those of actual practice. Some years ago there were alternating-current machines brought into the market, mainly, he thought by Messrs. Siemens Bros., that worked at a very low voltage, 40 or 50 volts. Of course, such machines had no *raison d'être* for modern work. Those machines had a large number of circuits in parallel, and it was at first a source of wonder to him how much power those machines contrived to absorb when running light and doing no work. At first he assumed it was due to eddy-currents in the clamps holding the coils together. Then he found those clamps did not heat, and he could not account for it on the assumption that it was all due to eddy-currents. He came to the conclusion, then—and all that Mr. Mordey had said confirmed it—that the cause of that very low efficiency, that relatively enormous waste of power at light load and no load was simply the cross-connections in parallel of the different coils, the coils themselves not being equal among themselves, or the pairs of poles not being of equal power, therefore the internal currents running in and out the cross connections of the armature wasted the power given to the machine.

The meeting then adjourned

THURSDAY, MARCH 9TH.

*Prof. SILVANUS P. THOMPSON said that if they could run a motor without any load whatever, even without friction on the armature, they would, of course, require no current to drive it round ; it ought to run without any effort. In that case the curve, which in Fig. 6 bends down, and comes to a minimum at some point above the zero line would, of course, go down to zero. They would then have for the curve two straight lines meeting at a point. If the field-magnets of a motor were excited exactly up to the proper point, its electromotive-force would precisely balance in every instance the electromotive-force coming in from the outside. The two waves were absolutely symmetrical, but opposed. But if it were not excited at exactly the right amount, a machine running at its proper speed will give back an electromotive-force not equal to the applied electromotive-force ; and then there would be a current, either leading or lagging in phase, according to whether the motor was under-excited or over-excited If the magnetism of the motor-field were at any moment proportional to the exciting number of amperes, then he presumed those two sides of the curve would be straight lines. But they knew the magnetism was not proportional. The only reason why it was nearly symmetrical was because near these lines the field was not excited to anywhere near what one called the saturation point of excitation. He happened to have been reading that day the proceedings of one of the American Societies, and was very much amused to see a communication, a formal communication, read by an engineer who was running a certain Manhattan station with alternating-current machines in America He was describing the advantage of the newest system of switchboards, which he said was a beautiful switchboard, "marbleised in imitation of Tennessee marble," a real ornament to any station. It was contrived on the following principle :—There were 17 different circuits going out from that station to the lamps, and 19 different alternating machines, and the arrangement was such that by no conceivable possibility could a man, desiring to make a mistake, put one of those machines into parallel with any other machine. There could hardly be a more striking commentary upon the difference between one country and another than the Paper discussed here to-night and that read in America, showing how the practice in the two countries has gone so absolutely in two different directions.

*Dr. FLEMING then exhibited and described a new wattmeter, in which the shunt coil was excited by means of transformers. In ordinary wattmeters the fixed or series coils were firmly fixed, but in this instrument they were carried by two pieces of wood, and were capable of being pushed together or drawn apart from the screw, so as to bring them nearer or move them farther from the movable coil. Instead of fixing the mercury-cups, they were carried on the coil itself. The object of that was to induce perfect symmetry in getting a current into the movable coil.

*Dr. HOPKINSON was of opinion that the general method of testing the electrical appliances, a particular case which Mr. Mordey had so well described in his Paper, had really two advantages. The first was that they were able to test their appliances with the expenditure of a very small power, namely, the power which is wasted in those instruments ; the other was that they could carry out their test with a very much greater degree

Hosted by Google

of accuracy. Suppose, for example, in the combination of the two appliances there was a loss of 10 per cent., and they could make their measurements with a power of only 1 per cent., then they could make their test of efficiency to an accuracy of one-tenth per cent., or thereabout. That second advantage he was not sure whether Mr. Mordey put in sufficient prominence. The advantage, however, existed whether the dynamometer were used or whether they used an arrangement, proposed afterwards by Lord Rayleigh, in which all the measurements were made electrically. About a year ago he tried some experiments with transformers by this method. The method then adopted was substantially the same—that is to say, they measured the power transmitted from one instrument to another, and measured directly the loss in those two instruments. As applied then, that method had only the second of those two advantages ; it had not the first, of economising the power required to drive the combination. Immediately afterwards almost, Prof. Ayrton and Dr. Sumpner published a description of tests of transformers which realised both those advantages. They were such that economy of power was secured as well as greater accuracy of testing. His method, however, was designed to give other information than the mere testing of efficiency. As the transformers were sent to him, undoubtedly the test of efficiency was that to which he was asked to address himself, but having them in his hands he desired to get out of them all the information that was obtainable. Mr. Mordey had referred to the possibility of testing a single continuous-current machine in which there were two equal circuits with separate commutators by connecting the two commutators together in such wise, that the power developed electrically in one circuit would be used in the other to generate mechanical power again. A method applied in that way was, of course, as Prof. Ayrton had pointed out, open to the objection that it did not give a complete test of the mechanical properties of the machine ; they did not get the mechanical tortion applied to the shaft, and generally the mechanical properties of the machine were not tested thereby. It had also another objection, that if they had two coils connected in that way they would have no distortion of the magnetic field, for the current in one section of the armature would be counterbalanced by the current in the other, and the sparking-point of the transformer would be the same as if there were no current at all passing in that machine. In the generality of continuous-current machines this was no great inconvenience, and probably did not introduce any serious error into the accuracy of the efficiency tests, but he could well imagine machines in which there would be a greater efficiency shown when tested in this way than if tested with two separate machines coupled together mechanically and coupled together electrically. In the case of the brush-dynamo used as a generator, it was well known that the pole-pieces heated, and that they heated particularly in that part where the armature was pulled away from the pole-pieces ; if, on the other hand, the machine was used as a motor, they heated at that part of the pole-pieces to which the armature approached. If they arranged a machine with two commutators upon it in such wise that the current in one section of the armature opposed that of the other, they would have this heating considerably diminished, and he thought it probable that they would in the latter case get a higher efficiency than in the first. Mr Mordey's method of testing alternators in the single machine was open, to a certain extent, to the same objection.

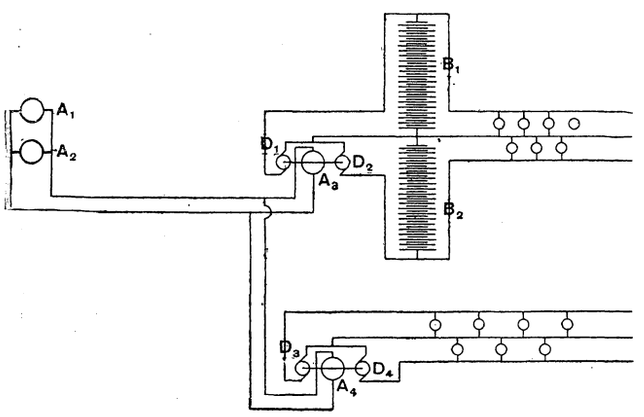

Diagram I.

*Mr. KAPP said it might be interesting to the meeting if he mentioned a practical example where the behaviour of alternators when used as motors had been verified in accordance with Mr. Mordey's, Fig. 6. He referred to the power transmission by alternating-current put up two years ago in Cassel. Let diagram I. represent both the generator and motor stations. Imagine A_1, A_2 to be two alternators coupled in parallel. The current was sent to Cassel several miles distant through a concentric cable having considerable capacity. The current at Cassel splits up into two branches leading to two stations in different parts of the town, where the dynamos D_1, D_2, D_3, D_4 were driven by the alternators A_3, A_4. The supply was by low-pressure continuous-current. At one of the sub-stations there was a battery, and both sub-stations were connected to the main on the three-wire system. That was to say, each sub-station had two continuous current generators, and between them was an alternator coupled rigidly to the continuous-current machines. When this plant was started the man in charge made the discovery that he could vary the armature-current by adjusting the current through the fields. The man there simply discovered it for himself ; he found, "If I can work my station with 20 amperes instead of 30, so much the better," and adjusted his rheostat in the field until he got minimum current. He (Mr. Kapp) then investigated the matter, and worked out from the characteristic curve and from the self-induction of the motor-alternator what would be the armature-current in order that the machine might do a certain amount of mechanical work. The result of this investigation was plotted on the curve (Diagram II). It referred to a 10-kilowatt 2,000-volt machine. He found that if the excitation was such that it would give 2,000 volts when working as a generator, it would have minimum armature-current, when giving 10 kilowatts as a motor : if it was excited to a higher degree, so that it would, as a generator, give 3,000 volts, the armature-current required for the same 10 kilowatts would be greater. It would also be greater if they excited the machine less. There was a still more interesting point in connection with that curve. If they looked at the curve they would find that it was not a straight line ; that they also found in the other diagram. Now, what did that mean? It meant that if they reduced the excitation below a certain point, the armature current would become very large—about $2\frac{1}{2}$ times the minimum. But if they reduced the exciting current below that point, they would miss the curve altogether ; that was to say, the machine would electrically break down—fall out of step. That was rational, for by experience they knew that alternators would support from two to three times their normal loads before being thrown out of step. The dotted curve was the curve which resulted when they neglected, and the full curve when they took armature reaction into account. When the curves bent back on the left it showed that the working was unstable, in fact, the dotted portions of the thick curves referred to impossible working conditions. He had drawn the curves for three different powers —20 kilowatts, 10 kilowatts, and 1 kilowatt—and he then tested the machine ; he did not get any test exactly at 20 kilowatts, or 10, or 1, but the circles showed the curves which were obtained to be of the same general character as those which had been determined theoretically.

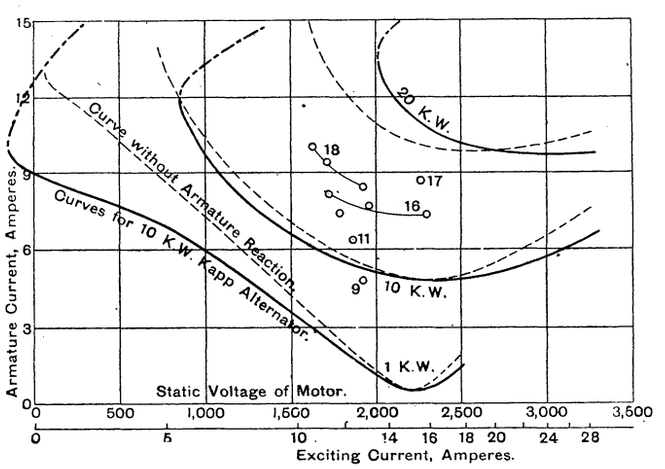

Diagram II.

*Mr. HARRISON said that Mr. Mordey had acknowledged his indebtedness to Dr. Hopkinson's earlier Papers on this subject, and had stated that his experimental results had been anticipated. He was afraid that most practical engineers regarded those earlier Papers of Dr. Hopkinson's rather in the light of that block of marble in which there lay a statue of great price, and he doubted if many engineers had ever chipped off the mathematics in which these great truths lay hidden. If the curves in these Papers were read side by side with the mathematics which followed, the whole matter was explained simply enough. But, unfortunately, there were those who read the curves without the text. There was an electromotive force which was not shown on the curves. They did not in fact tell the whole tale. If they had three Daniell cells in series, they had a battery which had an electromotive force of three volts ; if they reversed one of these cells, it neutralised the electromotive force of a second cell, and they had a battery electromotive force of one volt. Apply Ohm's law to any circuit to which it might be applied and it would work ; but if it were still maintained that the electromotive force of such a battery was three volts, there would be an apparent contradiction of Ohm's law such as is frequently supposed to be the case with alternating currents. The statement that a 100-volt alternator could drive a 200-volter as a motor was true only with the qualification that when it was doing so, the 200-volter was not giving 200 volts. Mr. Harrison then described some experiments with an old Siemens alternator at Faraday House in which the alternating current from the armature throbbed, or pulsated, when run as a motor from the London Company's mains, and the needle of the ammeter in the field circuit excited from secondary cells pulsated in the most marked manner also.

*Mr. SWINBURNE, in a written communication, observed that a full load test did four things. It tested the armature for mechanical strength, the bearings for full load behaviour, the armature coils for heating, and the field for heating under full excitation. If an efficiency test were also needed, the test gave it, including losses in bearings with belt or ropes on, losses in the armature due to full-load current, and losses in the field under full excitation. These tests were not fully carried out in Mr.

Hosted by Google

Mordey's method. Mr. Mordey seemed to think an efficiency test should be taken with the belt off. He would submit that was absurd. The loss due to the belt occurred in practical use and must therefore be included in the machine losses. The engineer might equally justly say his engine should be run without a belt, because the belt was not part of the engine. Of course the efficiency came out higher without the belt, but the too common habit of making out a high paper efficiency was to be deprecated. He could not agree with Mr. Mordey as to the details of parallel running. To secure parallel running they must not consider the dynamos only, but the whole station. A factor commonly neglected, and not referred to by Mr. Mordey, was the engine-governor. To run a number of alternators in parallel off separate engines, each with its own independent speed-governor, was as foolish as to run independently-governed engines on to one shaft. When dynamos were in parallel, the excitation controlled the idle component of the armature current, and the steam admission controlled the active component, that is, the output. Every station dynamo should, therefore, have a wattmeter to show whether the steam supply was right and whether the machine was doing full work, and an idle current indicator to show whether it was over or under excited. At present, people did not study the question as a whole. They looked at a little bit of the problem, the dynamo for example, or its armature, and they neglected the engine, the exciting arrangements, the governors, the throbbing of a slow-running engine, and the steam-pipe connections. They then coupled two alternators in parallel. If they burned up they said the alternators did not run in parallel; if they did not burn up they wrote a testimonial for the maker of the alternator.

Mr. CROMPTON said that Mr. Willans had been working with various forms of electrical governors for keeping alternators equally loaded, but he thought the view he took latterly was that it would be better to do away with separate governers completely, and put one governer on the main steam-pipe. All methods that took off the side pull of the belts gave far too favourable results of the efficiency of the machines from a mechanical point of view. The effect of the absence of the side pull was shown very plainly in the very high efficiency that makers of direct-driven dynamos had been able to show. If makers of steam engines removed the side pull, efficiencies of 94 and 95 per cent. were obtained in practice. He would like to ask Mr. Mordey whether he had not availed himself of the means of which they had all availed themselves in the past, and that was attaching an alternator to a Willans engine and submitting it to the very excellent series of tests which had been going on for some years past at Messrs. Willans' works. It would be most interesting to see how far tests thus obtained would corroborate the efficiencies obtained by Mr. Mordey with the method laid down in this Paper.

*Dr. SUMPNER said that every alternator really consisted of a number of small machines in series, and what Mr. Mordey had done was to connect some up as motors and some as dynamos, and to use the Hopkinson method in connection with the combination. One of the great advantages of Dr. Hopkinson's method was that they could not only measure the losses accurately and do the whole thing with a very small amount of power, but they could very easily separate the losses from one another. He had tested a 100 H.P. Phœnix alternator having 20 pole-pieces, first dividing them into 10 and 10 and using 8 amperes in one half and 18 in the other, and afterwards dividing them into 8 and 12 poles and using the same current through both. The results were not very accurate, but agreed together.

Mr. BAILEY described a method which had been adopted by Mr. Gordon in testing the Paddington alternators with a view of finding out defective coils.

Mr. WEEKES described some experiments with a Ferranti alternator to find if the self-induction of the alternator altered with an increased load.

*Mr. MORDEY said that there was one point that was raised by Mr. Harrison, and, as it really was a criticism of some of the results referred to by Dr. Hopkinson, he should be very glad if Dr. Hopkinson could briefly reply to that, or add it to his remarks.

The PRESIDENT said that he would be very glad if he would add it to his remarks. Unfortunately he had already ruled Dr. Hopkinson out of order. He took that opportunity of saying that as long as he was President he intended to confine the discussions as much as he possibly could to the Paper under discussion.

*Mr. MORDEY, in reply, said that Prof. Ayrton had criticised the method of circulating power, and had said that no indication was given as to whether the shaft was strong enough in the machine. That was quite true. As far as that was concerned, they knew quite well what shaft to put in for various powers and conditions, and he thought most engineers were always able to put in shafts they had every confidence in. They were quite satisfied about their bearings. Dr. Thompson had said that the conditions in a machine running in this way were not quite the same as when running as a generator or as a motor. That was quite true. There were slight differences, for example, the torque was in opposite directions in the two parts, but he did not think they amounted to anything as far as the accuracy was concerned or the Foucault currents were concerned, or any practical conditions which the test seeks to determine. Something had been said as to the unequal effect on the fields of the two parts of the machine, running with one portion running as a motor and the other as a generator. Some two years ago he described an experiment with an alternator in which one coil was taken out of the circuit and merely connected to a voltmeter. The other coils were then loaded from nothing up to full load and the excitation kept constant, and the volts shown by the idle coil remained perfectly constant. He took that to indicate that the reaction of the armature on the field was not appreciable. He thought Mr. Kapp's curve was not a good curve. It appeared that the machine was going to break out of synchronism at $2\frac{1}{2}$ times the best current. In his curve he got up to 20 times and did not break out of synchronism. With reference to Mr. Harrison's experiments, he (Mr. Mordey) had had a good deal of experience of alternators, and had tried to find the faintest difference of field-current when the whole of the armature-current was thrown off suddenly, and had never seen in his own machines the slightest flicker in the exciting current. Mr. Swinburne had criticised the modification of Dr. Hopkinson's method on grounds that were not quite fair. He was trying to test an alternator; he was not trying to test an engine, or a boiler, or a belt. Really the alternator had to be driven somehow, and for the purpose of his argument his machine might be direct-driven. As to the side pull of the belt, he did not think that was a very serious matter. He did not think the loss in the bearings was a difficulty, and did not think the reduction of efficiency by side pull of the belt was to be traced to the bearing, but to the belt.

PARLIAMENTARY INTELLIGENCE.

HOUSE OF COMMONS—THURSDAY, MARCH 9TH.

City and South London Railway Bill.

Mr. PICKERSGILL rose to move that it be an instruction to the Committee on the City and South London Railway Bill that they do insert a clause reserving to the London County Council a power to purchase the undertaking, after the expiration of a limited period, on terms similar to those provided in section 43 of "The Tramways Act, 1870." He remarked that he brought forward this motion on behalf of the London County Council. There were now before the House a batch of London Electric Railway Bills, by which it was proposed to provide London with a series of underground railways, traversing the metropolis in various directions, and worked by electricity, and all the projected lines were practically within the area which was now controlled by the London County Council. He asked the House to affirm the principle that the London County Council, as a local authority, should be empowered to acquire those railways, on fair conditions, at the expiration of a certain term of years, which he would leave the Committee to fix. The Joint Committee which, in the last Parliament, had considered the question of similar Bills, had in their report neither approved nor condemned the principle of purchase; they had simply ignored it. The question was, therefore, still an open one. These electrical railway schemes differed in one very important respect from other underground railways, as it was proposed to give them the right to acquire way-leaves at a certain depth under the surface, and even where the lines would pass under private property they would be subject to the Lands Clauses Act in regard to compensation. In order to avoid, as far as might be, the necessity for payment of compensation, the routes had, whenever practicable, been marked out so as to follow public thoroughfares. A great advantage would thus be secured to the railway companies, and the public ought to receive some equivalent in return for parting with their rights. It was no answer to his contention to say that the companies would be put on terms of having to provide cheap trains, for this condition was now imposed upon all new lines running into the metropolis and having a suburban traffic. This was, he contended, emphatically a case in which compensation could most properly be given by providing that, under certain conditions, the community should have the right to acquire the undertakings after a specified number of years. This was no new principle. Under the Act of 1844, the public had a right of acquiring, under certain conditions, every railway in the country. From the point of view of the promotors of this Bill the sting of the proposed instruction seemed to rest on the term of years at the end of which the right of purchase might be exercised. It was clear that a term might be fixed which would have no effect on the financial prospects of the company. The essence of the case turned entirely on the number of years at which the term was fixed, but that matter would be for the Committee to decide hereafter. There was no wish on the part of the London County Council to crush out legitimate commercial enterprise, but the conditions of purchase might be—and must be—adjusted in such a way as not to interfere with the development of electric railways. In this connexion the story of electric lighting was not uninstructive. By the original Act the term was fixed at 21 years, which, undoubtedly, had the effect of checking electric lighting enterprise, but this term was afterwards altered to 42 years, and this stimulated electric lighting again. The right course was not to reject the principle of purchase, but to be careful that a term of years was fixed which would be suitable to the particular enterprise concerned. In this case the duty of fixing the term would devolve upon the Committee. The promotors of these electric railway Bills had shown great inconsistency. At one time they drew a most glowing picture and said that within seven years, if the means of getting about which these projects would afford were provided, the number of passengers annually carried in London would be no less than 400,000,000. In the case of the Baker-street and Waterloo line it was estimated that the number of passengers would be 60,000,000 annually, which was far in excess of the number carried on the Metropolitan District Railway. The broad ground upon which he based this instruction to the Committee was that the public had a right to acquire, upon reasonable conditions, all the means which were essential to the life of a great city and which partook of the nature of monopolies, whether concerned with water, gas, or locomotion. It was this simple proposition which he asked the House to affirm. He concluded by moving the first instruction which stood in his name.

Mr. BOULNOIS said these questions did not receive proper consideration in the London County Council. They were brought forward on the reports of committees, and those reports were usually circulated by the last post on Saturday night, so that members got them on Monday, the day before the discussions took place. Almost every proposition brought before the Council was closured after insufficient debate, and in the interest

Hosted by Google

of the ratepayers of London he opposed this proposal on principle, because to carry such an instruction would be absolutely in restraint of all private enterprise. The County Council did not intend to stop at tramways; they wanted to acquire the railways, the omnibuses, the steamboats, and the docks.

Mr. STANSFELD regarded the instruction as mandatory, directing the Committee to pursue a certain course whatever their own opinion might be; and, though the instruction was in order, it was unusual.

Mr. WHITMORE urged that the effect of the instruction would be to render private enterprise in tramways impracticable. Even if the proposal had any weight, the proper way to proceed would be, not in this piecemeal and accidental manner, but by a general public Act, which would have every opportunity of being considered in the House. He asked the House to reject the instruction, which would prevent most necessary railway projects from being carried out.

Mr. BURNS said it seemed to him that hon. members wished to deny to the largest city in the world powers which they were prepared to give to Birmingham, Glasgow, Manchester, Liverpool, and other large towns. The County Council had no desire to restrict private enterprise, provided it was consistent with something like the homogeneous government of London from a physical point of view. The request now made was, he held, perfectly reasonable, and ought to be conceded.

Sir J. LUBBOCK hardly thought the House would be disposed to refuse to London in a matter of this kind powers which it would give to Birmingham or Manchester. But that was not the question. He did not think the London County Council had reconsidered this matter since the Joint Committee reported upon it; and, therefore, though they were last year in favour of such powers as were sought by the instruction, the House could not regard the hon. member's claim to speak for them now. There was a great deal to be said for giving local authorities power to acquire railways; but, speaking for the present, the real interest of London was to improve its means of communication with as little delay as possible. Therefore, having regard to the statement of the Chairman of the Joint Committee, that such an instruction as that proposed would discourage private enterprise, he thought it better that the Bill should go to the Committee in the usual way.

Mr. MELLOR said, while he expressed no opinion as to the purchase of railways by the State or by local authorities, that if that were to be done it ought to be done by a public Bill. The present proceeding was a mode of evading the Standing Orders of the House; and, if it were assented to, it would be possible to engraft upon some small, and perhaps insignificant, Bill a great public change, which the House might wish to take some time to consider. A mandatory instruction ought to be very carefully scanned before being adopted, because under it the hands of the Committee were tied and their jurisdiction was practically nullified on matters of very considerable importance.

Mr. BALFOUR said the House would be grateful to the Chairman of Ways and Means for the very able guidance he had given them. He had shown that, whatever might be the merits or demerits of the abstract proposal of the hon. member, at all events, the House was asked to consider it in a shape which made it absolutely impossible for the House to accept it. For his own part, apart from that which was more an objection of form, he had two objections in point of substance. The first was that the acceptance of such a proposal would absolutely kill the investment of capital in the metropolis, and would render it unsafe for capitalists to come forward with projects of this sort, knowing that they would not reap the benefit of them. Secondly, he looked with very grave apprehension upon any scheme that would enormously increase the position of municipal bodies as direct employers of labour. They had seen in that House how much their own business was hampered by the fact that the country was itself an employer of labour, and night after night was taken up by discussion arising out of that fundamental fact.

The House divided and the numbers were:—

For the instruction	129
Against	242
Majority against	113

MONDAY, MARCH 13TH.

On Monday, before a Committee of the House of Commons, presided over by Sir John Kennaway, the two Bills of the City and South London Railway Company, for an extension of time for the construction of the line from Stockwell to Clapham, and for the extension from the City to Islington, were considered. Mr. Pembroke Stephens, Q.C., Mr. Rigg, and Mr. Claude Baggallay appeared as counsel for the promoters. Against the Clapham Extension there was only the Lambeth Vestry, represented by Mr. H. J. Smith, the vestry clerk. Against the Islington Extension Bill Mr. Meysey Thompson appeared for Mrs. Dora Twyford and Colonel Twyford; Mr. Worsley Taylor, Q.C., for the Orphan Working School, Mr. Littler, Q.C., and Mr. Monckton for the Corporation of London; and Mr. F. A. H. Terrell for Mr. Marcus H. Voss.

Mr. PEMBROKE STEPHENS in opening the case for the promoters explained the manner in which the Bills proposed to extend the existing lines at both ends, and said that when the original line was sanctioned, the idea was that it was to be worked by cable, but, as the Committee knew, there had been a very rapid advance in electrical knowledge of late years, and before the line was carried out, what at one time was only a theory was found to be quite within practical limits, and the system then adopted for working the line was that of electricity. The line had now surmounted all the difficulties which were experienced in the early part of its career. Its success had been so great and so rapid that they were hardly able to carry the traffic, over twelve million passengers having been carried during the short period which had elapsed since its opening. The Bill did not propose to interfere with the present station at King William-street, but to get the advantages of a second line on a different level which, starting from the Borough Station, would pass under the river to the right of London Bridge and beneath the King William-street Station up to the Angel, so that the two lines would be distinct. There would be four new stations between King William-street and the Angel, at Lombard-street, Moorgate-street, Old-street and Duncan-terrace.

The CHAIRMAN: Do you connect with the Oxford-street line?

Mr. PEMBROKE STEPHENS said that they would cross that line, and there would be a means of exchange with it. There would not be a physical running into it, because the lines were at right angles; but there would be the usual power of interchange by means of a subway. Having referred to the congestion of traffic and the thickly-populated character of the district which the line traversed, he proceeded to explain the method of construction and the advantages of the electrical working. Counsel urged upon the Committee the conclusions which had been adopted by the Joint Committee of both Houses which sat last year. He further explained that it was proposed to have subway communication with the London and Brighton and South-Eastern Railways at London Bridge; and, referring to the petition of the City Corporation against the Bill, said that that body had met them fairly and honourably, and there were no questions outstanding except with regard to a block of property at the northern portion of the line to which they attached considerable value, and for which they wished some special protection.

Mr. J. H. GREATHEAD, the engineer to the line, was then examined by Mr. Rigg, and bore out the opening statements of counsel, and said that as the original line from the Elephant and Castle to the Monument was laid out for working by cable traction the gradients and curves were rather severe for electrical traction, and the new line from the Borough into the City would give both better curves and better gradients. The sharpest curve on the new line would be twice the radius of the sharpest curve on the existing line, and the gradients would be 1 in 90 as compared with 1 in 30. The line would be laid in the London clay at a depth of from 50ft to 100ft. below the surface. There would be two generating stations, one at each end of the line.

Mr. RIGG: What has been your experience of electricity as a motive power on the City and South London line?

The WITNESS: At first, soon after the opening, we had a good deal of trouble with the motors, but now that is entirely overcome and the working of the line is exceedingly smooth, and certainly much more so, I think, than that of any other suburban railway coming into London. There is hardly any delay, and there has never been any trouble at all at the generating station in connection with the supplying of power to the trains.

Do you find that, using electricity as the motive-power, you can run a number of light trains at very short intervals?—Yes. One great advantage is that you can run your trains at very short intervals with no great addition to the expense. For instance, last half-year the trains ran 26,000 miles more than they did in the previous corresponding half-year and carried half a million more passengers, but the working expenses were not increased at all.

In response to further questions, the WITNESS said that the average speed on the new line would be 14 miles an hour, including stoppages, the whole journey from the City to Islington being done in about eight minutes, while from Lombard-street to London Bridge would occupy two minutes. Access to the stations would be by means of lifts and stairs, and the total cost of the railway, including land and contingencies, but exclusive of equipment, would be £706,633.

The WITNESS was cross-examined by various learned counsel as to possible damage to property of the clients whom they represented, but said there was nothing which could not be covered by protective clauses.

Mr. PEMBROKE STEPHENS, in reply to the Chairman, said they were prepared to call witnesses who wished to have the travelling benefits which the line would give, but

The CHAIRMAN said it was self-evident that there were a great many people to be carried in the direction in which the line went, and the Committee would not require any evidence on that point. He understood that since the matters were under consideration last June the financial position of the Company had very greatly improved.

Mr. PEMBROKE STEPHENS said he believed the debentures were fully-paid, the Preference Shares fully-paid, and that there was a certain modicum of return to the original shareholders.

The CHAIRMAN said that a great deal was made in regard to the new lines last June, that the whole scheme was an utterly impossible one as regarded any financial success; but he took it that that had been settled now. The Committee were satisfied on that point.

Mr. PEMBROKE STEPHENS said that if the Committee were satisfied as to the traffic and finance, as he had given them the best engineering evidence, he would close the case for the promoters. The preamble was practically unopposed, as regarded both Bills.

The CHAIRMAN declared the preambles of both Bills proved, and adjourned the consideration of clauses till Wednesday.

At the sitting of the Committee on Wednesday it was stated that clauses had been agreed to between the City Corporation and the promotors, and the Committee subsequently adjusted clauses for the protection of the Orphan Working School and other petitioners.

The City Lighting.—Some of the City arc lamps were recently extinguished by a short-circuit brought about in a somewhat curious way. One of the night stokers inadvertently tipped hot ashes over a conduit, and melted the insulation at this spot.

LEGAL INTELLIGENCE.

Unauthorised Telephone Poles.

At Glasgow last week Sheriff Murray had before him a petition at the instance of the Glasgow Police Commissioners against Mr. A. Erskine Muirhead, Cart Forge, Crossmyloof, in which the Commissioners craved that the defender be interdicted from erecting or continuing to erect in Norfolk Lane and Abbotsford Lane telephone poles and wires thereon, or in connection therewith, until he first obtained the permission of the pursuers to do so, and that the defender be ordained to remove any such poles and wires, or part thereof, that he may have already erected without permission, and, failing his doing so, that the Commissioners be authorised to remove these at the expense of the defender. The pursuers averred that the public streets of the city were vested in them, that Norfolk-lane and Abbotsford-lane were public streets, that within the last few days the defender had commenced to erect poles in these lanes, that the poles were 25ft. high, 3½in. in diameter at their base, were fixed to the adjoining walls, and that the wires, when attached, would run over the public streets, and that they had never authorised or permitted their erection. They further averred that in October, 1890, the defender applied to them for permission to erect telephone poles in Abbotsford-lane, and was refused, and that he had now, in disregard and defiance of their decision, commenced to erect the poles and wires in question.

Mr. JOHN LINDSAY, assistant Clerk of Police, asked his Lordship to continue the interim interdict he had granted on Saturday last.

Mr. MUIRHEAD explained that having got the consent of the private owners in the lanes he did not think it necessary to apply to the Police Commissioners for authority, and he referred to certain lanes in the west end where he had erected similar poles without further authority than that of the private owners. He explained, too, that since the interdict had been served he had applied to the pursuers for the necessary authority.

Mr. LINDLEY, in reply, pointed out that the west-end lanes referred to by the defender were private streets, whereas the lanes in question were public streets, and that, therefore, there were more than the private owners to consult.

The SHERIFF continued the interim interdict already granted till further orders, reserving all pleas.

Challis v. Woodhouse and Rawson United (Limited.)

This was an action brought in the Lord's Mayor's Court on Tuesday, before the Recorder and a common Jury, by Mr. C. E. Challis to recover £50, two years' royalties payable in respect of a certain patented invention licensed to the defendant company. The plaintiff was the joint patentee of a certain invention for electric switches, which by an agreement of June 20th, 1890, he licensed to the defendants in consideration of an alleged minimum payment of £25. He claimed two years' royalties under this agreement, and a letter was put in in which the defendants offered £25 in settlement. Ultimately it was agreed that a verdict should be returned for the plaintiff for the amount claimed, leave being given to apply for a new trial, which it was understood would be granted.

Thomas Connolly v. The International Okonite Company (Limited).

An action was brought last week by Mr. T. Connolly, late Works Manager of the International Okonite Company (Limited), of Manchester and London, at Manchester, to recover damages for wrongful dismissal, and arrears of salary and expenses. The Company paid into Court the amount of arrears of salary and expenses, but denied all responsibility for wrongful dismissal. The case was brought before Mr. Justice Wills at the Assize Court, and after Mr. Connolly had been put into the box, and came under cross-examination by Mr. Gully, Q.C., M.P. (for the Company), the Judge and jury stopped the case, and gave a verdict for the defendants, with costs, the amount of money paid into Court for arrears of salary and expenses to remain there pending the taxation of costs.

CORRESPONDENCE.

COST OF A STEAM HORSE-POWER.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: There was an article in *The Electrician*, of January 24th, dealing with the cost of power, in which there were some courteous references to myself for which my thanks are due.

Towards the end of this article you state that "to these figures may be added the annual cost of steam-power according to the independent, but remarkably coincident, estimates of Mr. Swinburne, and of Messrs. Cross and Bevan, namely, £6. 11s. per horse-power per year of 8,760 hours." This estimate is, no doubt, a low one, but I should not greatly dissent from it, if certain conditions favourable to economy of production of steam-power were understood to be assumed. But what I should like to know is, what are the causes of the difference of this estimate and the actual cost shown in the returns of electric lighting stations.

From a table published in *Lightning* and, which, probably, is very well known to electricians, I find that an electrical unit is generated rather more cheaply at Bradford than at any other central station in England. In dealing with the Bradford figures, I discard the cost under the heading "Redemption Fund," and the cost under the heading "Salaries." Further, I discard half the cost under the headings "Repairs and Maintenance" and "Depreciation," because there appear to be included in these items more than is fairly chargeable to cost of power. The result is that at Bradford the cost per unit, mainly attributable to cost of producing power, is 2·1 penny. Now the mechanical value of an electric unit 1⅓ H.P. hours, and if we take the average efficiency of the dynamo at 0 85, then 1·57 effective horse-power hours must correspond to a unit.

Calculating on this basis, it appears that the cost of an effective horse-power per year of 8,760 hours at Bradford is £49, or, say, seven and a-half times the estimate given in your article. This is at a station where the cost per unit is lower than at any other station in England, and where the coal used is, according to Mr. Shoolbred's statement, partly "nuts," costing 8s. to 10s. a ton, and partly slack, costing half as much.

I am really interested in understanding how so great a difference arises. Of course, I suppose it will be said at once that Mr. Swinburne and Messrs. Cross and Bevan estimated the cost for an unvarying load, and the difference is due to the fact that an electric-lighting station works with a varying load. Be it so. No doubt the variation of load is disastrous, but the most careful estimate of the effect of a varying load on the efficiency of engines and boilers leads me to think that this cause alone ought not to be so disastrous as to explain more than a third of the difference between the estimate and the Bradford result.

However this may be, I think the cost, looked at in this way, is instructive, even if necessarily the method of calculation is open to some criticism. I add some other figures obtained in the same way.

—	Cost per unit (pence).	Cost per effective H.P. per annum (pounds).
Bradford, 1891	2·10	48·76
St. James's, 1892	2·60	60·37
Kensington, 1892	2·90	67·34
Westminster, 1892	3·49	81·04
Chelsea, 1892	4·07	94·50
Metropolitan, 1891	4·35	101·01
Eastbourne, 1891	5·51	127·94

—Yours, &c., W. C. UNWIN.

P.S.—It occurs to me to take the cost of coal and petty stores only, which I suppose must be exclusively charged to production of power. Proceeding so, the following is the cost per horse-power per annum, exclusive of all charges for labour, for repairs, for interest, or for depreciation :—

Cost per horse-power per annum for coal and petty stores only.

—	Cost per unit (pence).	Cost per effective H.P. per annum (pounds).
Bradford	0·63	14·6
St. James's	1·06	24·6
Kensington	1·11	25·8
Westminster	1·29	30·0
Chelsea	2·93	68·0
Metropolitan	2·55	59·0
Eastbourne	2·40	56·0

SINGLE-PHASE ALTERNATING MOTORS.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: My attention has been called to an article appearing in your valuable journal on "Non-synchronous Motors for Ordinary Alternating Currents," by C. E. L. Brown.

I beg to state that motors of the kind he describes were not unknown to the art, as a reference to my United States patent

Hosted by Google

No. 407,844, filed November 17, 1888, will show. In fact, I sent to the Paris Exposition of 1889 a small single-phase alternating-current motor with arrangements for starting, which motor was built in accordance with the principle pointed out by Mr. Brown as arising from his own observations. Not long after I made my experiments which led to the transformer motors, I found that such a motor could have its armature coils kept on short circuit and run in either direction after a start had been given to it. The original motor had a single inducing or field circuit, and an armature with three coils and a commutator similar to that of a Thomson-Houston arc machine, and connected, movable, straddling brushes, whereby the period of short-circuiting of the armature coils could be increased, after starting, to include the whole period, and maintain them on closed circuit.

This was followed by the construction and working of many such machines, with different arrangements of winding and means for starting. I have no hesitation in saying that had it not been for the comparatively high frequency of alternating currents in use, namely, 125 to 130 per second, a large extension of the use of such motors would have taken place by this time in the United States.

The motor on this principle, which was exhibited at Paris in 1889, was described in a number of the technical journals at the time. It had a commutator which was only used in starting. The rotating part had its coils connected with the commutator, and the brushes at starting were included in the alternating-current circuit driving the machine in series with the inducing field. At a fairly good speed a centrifugal device inside the commutator short-circuited the segments and placed the revolving coils thereby on a maintained short circuit, and the motor at once speeded up to nearly synchronism. Even at 125 periodicity the motor was efficient, the only drawback being that its weight output was less than could have been obtained with lower frequency. The principle of such single-phase motors may be illustrated very prettily as follows:—Let a coil with iron wire core be energised by alternating currents so as to produce an alternating field, and let a wheel be made up of iron discs at the centre, around which is a rim or band of copper overhanging the edges of the discs. This wheel is mounted on pivots and started in rotation mechanically in either direction. After this it will increase in speed and torque up to a certain point, depending on the frequency of the currents in the coil and the friction to be overcome. That the direction of motion is indifferent may be shown by turning the wheel on a vertical axis so as to present to the pole the opposite end of a diameter. The rotative action I have formerly described as being due to translation lag—that is a lag due to the traverse of a conductor conveying current past the pole, whereby the action of the current in that conductor becomes displaced in the direction of motion, and produces a moving field, the iron mass or body tending to accommodate itself to the direction of the lines in the moving field.—Yours, &c., ELIHU THOMSON.

AMERICAN INSTITUTE DEFINITIONS.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: In your editorial notes on page 377 of your current volume, dated February 3rd, you point out that the definition of "impressed electromotive force" suggested by the sub-committee on programme for the Chicago Congress, appointed by the American Institute of Electrical Engineers, is not well worded. Will you kindly permit me, as a member of that committee, to defend this definition against your criticism?

Your argument as to a flaw in the accuracy of the definition may presumably be expressed as follows:—If the impressed E.M.F. in a simple circuit containing both inductance and resistance is "the ratio of the total activity to the instantaneous value of the current," this ratio should become zero the moment that the impressed E.M.F. is made to vanish. But we know that the current does not then immediately vanish, and as the existence of that current implies the expenditure of work, therefore the activity, contrary to the definition, is not zero. Our word "total," however, is intended to include the electromagnetic as well as the galvanic activity. In this sense I think you will admit that the definition is true. For if the impressed E.M.F. be denoted by e,

$$e = cr + l\dot{c}$$

$$\therefore ec = c^2 r + lc\dot{c}$$

In the latter equation the left hand member ec is, of course, the instantaneous activity in the circuit, positive when e and c are of like sign, and negative in the opposite event. But if, with c finite, e is suddenly made to vanish $c^2 r = -lc\dot{c}$, and $\dot{c}$ must have contrary sign to c. As you have stated it, the dying magnetism sustains the current; but that dying magnetism is a loss of energy to the circuit, and as such a negative activity, equal and opposite to the activity always positive in $c^2 r$.

Or regarded from a slightly shifted standpoint, if we could envelop the whole circuit with a shell of material perfectly impervious to heat at the instant the E.M.F. was withdrawn, the energy then in the circuit would remain unaltered. For the magnetic energy existing as vortical motion, stress, or in some other manner, through the environing medium, would, we know, be withdrawn, and would exist thereafter as molecular activity in virtue of an exalted temperature of the conductor or medium. The spin motion would become oscillatory motion. Since the space within the shell as a whole would neither gain nor lose energy, its total activity at any moment must be zero.

While you may, perhaps, replace our definition by some alternative more clear or desirable, I would submit that you will not, in so doing, take one that is more nearly true. The alternative you allude to applies to voltage in general, rather than to impressed voltage.—Yours &c.,

Orange, N.J., March 2, 1893. A. E. KENNELLY.

[The distinction consists merely in the meaning of the word activity. If the activity of the source means the rate at which it supplies energy to the circuit, the definition is quite accurate —ED. *E.*]

AMBERLEY ROAD STATION.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: Referring to the article on the above in your last issue, we regret that the writer should have thought fit to charge us with supplying so-called "cheap German instruments" without knowing the facts of the case. The instruments mentioned were supplied with the full approval of the engineer of the Metropolitan Company under a very sufficient guarantee from the makers, Messrs. Hartmann and Braun, for their correctness.

The reason that the alternators were not made at our works was, that at the time the contract was placed with us (now more than four years ago) we were not equipped for building such large machines, and as we were exceptionally busy, and hurried delivery was required under heavy penalties, we were forced to place the order with our licencees in Switzerland. We need hardly say that since then we have set ourselves out for building machines of any size on the shortest notice.

In describing the means used for obviating the "hum," we would mention that the wood filling was placed between the pole-pieces of the field-magnets, and not between the armature-coils, as stated.—Yours, &c., JOHNSON & PHILLIPS,
Contractors for the Plant.

Old Charlton, Kent, March 14, 1893.

[We find nothing material to modify in the remarks in the article referred to. The instruments were, no doubt, "supplied with the full approval of the engineer," but, in thus approving, he obviously expected something better than the quality which was supplied. The instruments having been fully guaranteed, it does not appear that Messrs. Johnson and Phillips have any responsibility in the matter. It has been suggested that the serious errors were due to an erroneous adjustment for frequency, but this had been clearly specified in ordering the instruments. Allowance should always be made for little hitches or mishaps on the opening day, but at Amberley-road nothing of the kind was to be seen, and the performance of these instruments certainly cannot be called a mishap when any English instrument-maker of repute could supply instruments from stock not only guaranteed, but actually reading to one-half per cent. We willingly withdraw the word "cheap" if it can be construed to reflect upon the contractors.—Ed. *E.*]

DOUBLE-BRONZE WIRE.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: In your issue of the 3rd inst. we read the following:—"A new kind of telephone wire is being experimented with in Germany, consisting of an aluminium-bronze core with a copper-bronze envelope. It is said to have a low resistance, and to have great tensile strength."

The material to which reference is made in these lines is the patent double-bronze wire which we manufacture, and possibly it may interest your readers to learn something more about this wire. Besides the advantages mentioned in the above notice, it possesses the property of a quite extraordinary toughness. The wire stands a considerably larger number of bends than any bronze wire in existence, which, as every user of telegraph and telephone wires will know, is especially important in the work of erecting lines.

We make patent double-bronze wire to the following specifications:—

Gauge of wire (standard gauge).	Guaranteed		
	Breaking strain (lbs.).	Maximum electrical resistance (ohms per mile, at 60°F).	Bends of 180° over 5mm. radius alternate.
11	857	4·43	8 to 10
12	691	5·55	8 to 10
13	549	7·03	8 to 10
14	382	9·37	10 to 13
15	364	17·20	15 to 20
16	311	21·70	15 to 20
17	238	28·60	15 to 20
18	174	38·70	15 to 20
19	121	55·50	15 to 28
20	100	69·60	15 to 20

The above figures being guaranteed, the tests in reality will be found still more favourable.—Yours, &c.,

FELTEN AND GUILLEAUME.

Mülheim-on-the-Rhine, March 14, 1893.

THE HEILMANN ELECTRIC LOCOMOTIVE.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: On page 503 of your issue of March 3rd there is a note headed "The Heilmann Electric Locomotive," into which an error has crept. As a matter of fact, the locomotive which I am constructing, and which is shortly to be tried on the State railways, is not worked off accumulators. It comprises, as you say, a Lentz boiler, a Brown steam-engine, and a dynamo-generator; but the current produced actuates directly the electric motors keyed to the axles. The axles are four in number per bogie, and the entire locomotive is mounted on two exactly similar bogies. The generator is a 600 H.P. machine. The Northern Railway Company proposes to experiment with an accumulator locomotive, but I repeat that there is nothing similar in the two schemes. I am ready to give you any further particulars that you may wish.—Yours, &c.,

R. SCHMID.

Traction Électrique (Système J. J. Heilmann),
30, Rue de Grammont, Paris, March 15, 1893.

"THAT BLESSED WORD, 'INSTALLATION'!"

TO THE EDITOR OF THE ELECTRICIAN.

SIR: Mr. Selby-Bigge's reply is an intellectual treat that I have much enjoyed, and I regret that for want of time I am prevented from improving my mind by taking further part in a discussion with one so well versed in dialectics; but I must point out that the word which Mr. Bigge says is "happily not in general use" has long since been appropriated by bishops, priests, and others, in reference to whom it is very commonly employed in accounts of *the act of setting on a seat and giving possession of an office, rank, or order, with the customary ceremonies.*

In these circumstances ordinary folk should be content with some shorter, but none the less comprehensive, word, the use of which would, in my opinion, undoubtedly lead to a precision of statement now sadly wanting in most of the installationistical documents I have seen. If Mr. Bigge will send to me privately one of the numerous agreements he alludes to, I will turn it into bad English and return it to him.—Yours, &c.,

WM. H. MASSEY.

Twyford R.S.O., Berks, March 12, 1893.

[Mr. Massey might try his hand at editing our Trade Notes. To exclude the word "installation" from our editorial columns is not difficult, but we have long since given up any attempt to repress it in "Trade Notes."—Ed. *E.*]

TRADE NOTES AND NOTICES.

[*Notices for insertion under the above heading must reach the Office not later than first post Thursday morning. New Catalogues, Price Lists, and similar matter should be sent early in the week.*]

The 1893 Edition of "THE ELECTRICIAN" Electrical Trades' Directory and Handbook is NOW READY. This useful book contains over 1,000 pages, and several new and handy features have been added. Price 7s. 6d., post free 8s. 3d.; abroad 8s. 10d. Comparison with any similar electrical publication is specially invited.

TENDERS INVITED.—The Corporation of Huddersfield invite tenders for the electric wiring and fittings required for lighting a portion of their Market Hall by electricity. Specifications, &c., may be obtained from Mr. A. B. Mountain, Borough Electrical Engineer, Gas Works, Huddersfield, to whom tenders must be sent not later than April 1st next. Further particulars are given in our advertisement columns.

——— The date for the opening of tenders for the electric lighting of Santiago, Chili, originally fixed March 1st (see *The Electrician* for November 25, 1892), has been postponed until June 1st.

TENDERS ACCEPTED.—The Southend Town Council have accepted the tender of Messrs. R. E. Crompton and Co. for additional plant in connection with the Southend Pier Tramway, to the amount of £1,988.

——— The Burton-on-Trent Corporation have accepted the tender of Mr. H. Slater, of Ashby, for the erection of buildings for the central electric lighting station, at Wetmore-road, for the sum of £2,715. 2s., and that of Messrs. Hill and Smith, of Brierley Hill, for the construction of wrought-iron roofs for the central station, at £820. 19s. 5d.

RE MESSRS. F. SILVESTER AND CO.—The statement of affairs in this bankruptcy is published, and shows total liabilities of £3,869. 3s. 1d., assets estimated to produce £1,516. 9s. 9d., leaving a total deficiency of £2,352. 13s. 4d. The debtor ascribes his failure to bad trade and debts. The firm consists of Mr. Frederick Silvester, who purchased the business and stock-in-trade of the Castle Hill Foundry, Newcastle-under-Lyme, in 1884, and the loss of business appears to have arisen during the past three years. Included in the statement made by the bankrupt is the cost incurred in starting new electrical engineering, &c., business, viz., £500. There are 122 creditors.

BANKRUPTCY.—Edward James Bayly, electrical engineer, of 2, Selborne-street, Liverpool, has been adjudicated a bankrupt. ——Proofs of debts in the bankruptcy of Montagu J. Scott, trading as Montagu J. Scott and Co., electrical engineers, 11, South Molton-street, and 134, Regent-street, must be sent in to Mr. E. L. Bennett, 55 and 56, Bishopsgate-street, E.C., by March 28th.

TELEGRAPH MANUFACTURING COMPANY (LIMITED).—This Company, coincident with the completion of an enlargement of their cable department, and more particularly of their rubber plant, are issuing new editions of their copyright price lists of electric light cables, wires, mains, and flexibles, suitable for house, ship, under-underground, and aerial circuits. These lists are issued for office use, and also in pocket form, at a nominal charge of 1s. 6d. In all 1,371 varieties of insulated conductors are described and priced, the lists containing a specification, the resistance of the conductor, the current-carrying capacity at 1,000 amperes per square inch for a loss of one volt per 100 yards, and for a rise in temperature of 18°F. in casing, the thickness of insulation and the minimum guaranteed megohm per mile after 24 hours immersion in water

Hosted by Google

at 60°F. and one minute's electrification for vulcanised rubber cables and wires, the finished diameter, and the weight per 100 yards. There are 22 sizes of cables, each with 20 varities of insulation and finish, the same number of wires with 16 varieties of each, 22 sizes of twin and concentric flexibles for currents of from 0·43 to 50 amperes, with 20 varieties of each; also mains up to 1 square inch section for 1,000 volts, and concentric mains up to 37/14s. for 2,500 volts. In addition prices are given of cables and wires for concentric wiring. Perhaps the most noticeable feature of the lists is the ease with which prices can be found and compared with others, as the costs of different qualities of insulation for any conductor are given all in one line. Contractors will find the pocket lists useful, all the above information being given on a mounted sheet, which, when enclosed in its case, measures only 6¾in. × 3⅛in. × 3-16in., and yet the sizes of conductors and the prices are printed in type of a very prominent character.

Messrs. Rashleigh Phipps and Co.—This firm have secured contracts for lighting the following premises:—The Scottish Metropolitan Life Insurance Society, King-street, Cheapside: Messrs. Hudson Bros' Stores, Devonshire-square; Mr. J. L. Langman's house, Stanhope-terrace; Messrs. Kirkman and Sons', piano manufacturers, new premises, George-street, Hanover-square; The Pure Bread Company, Queen Victoria-street; and Dr. F. W. Andrews' new house, Welbeck-street; all of London.

The K.M.B. Portable Testing Set.—The testing set illustrated below has been specially designed by Messrs. King, Mendham and Co., of Bristol and London, for testing insulation resistances by the direct deflection method. The galvanometer, which has a 4in. silvered dial, is provided with a suspended needle; a series of shunts $\frac{1}{9}$ and $\frac{1}{99}$ is connected across the galvanometer, and terminals are provided for the battery connections and also for the insulation of cable and earth or return. The necessary contacts for testing are made by means of a spring held midway between two brass blocks with platinum points.

One block is connected with a 10,000-ohm coil which is provided for the purpose of taking the galvanometer reading with a known resistance; the remaining block is connected with the "insulation" terminal. By holding this spring against one block or the other, the two required readings can be taken. By this arrangement loose plugs are avoided and lists are quickly made; connections are engraved on the ebonite top, and printed instructions are inserted inside the cover of the box.

Mr. Guy C. Fricker.—The whole of the electric lighting arrangements for the forthcoming exhibition at Earl's Court have been entrusted to Mr. Fricker, who is also engaged in laying down a complete plant of gas-engines, dynamos, and accumulators, for the new offices and printing plants, of Messrs. Kelly and Co., at High Holborn, the installation being for about 400 lamps. Amongst recent plants completed by Mr. Fricker, is one for Messrs. Colls and Sons, at Lime Street-square, for 200 lights.

A Reservoir Drawing-Pen.—Messrs. Jackson Brothers, of Leeds, have brought out a drawing-pen with an ink reservoir in the handle. They have submitted a sample, and we have given it a trial. A cylinder, fitting in the handle, may be filled with ink. by pulling out a plunger. A slight push to the plunger serves to feed the pen with ink. The pen is necessarily larger and heavier than an ordinary one, and feels rather clumsy in the hand. The back nib in the sample which has been sent us is too springy, but this could easily be remedied. The reservoir arrangement works well, and is easily managed. The pen will doubtless be useful for some kinds of work, especially where heavy lines are wanted, and where an ordinary pen will only run a few inches without re-dipping and wiping.

Oil Engines.—We have received from Messrs. Robert Stephenson and Co. (Limited) a circular relating to the "Rocket" oil-engine, for which simplicity, ease and certainty in starting, and economy in working are specially claimed.

Dee Oil Company (Limited).—At Wednesday's sitting of the London Bankruptcy Court Mr. Registrar Emden presided at an inquiry into the promotion, business operations, and failure of the Dee Oil Company (Limited), which was promoted in May, 1888. The winding-up order was made in April, 1891, upon a creditor's petition. The accounts filed thereunder show total liabilities £58,410. 14s. 7d., of which £3,768. 10s. 2d. are expected to rank. The assets, valued at £51,582. 2s., were entirely absorbed by loans on debenture bonds, and the deficiency as regards contributories was estimated at £103,768. 10s. 2d. Sir John Stokes, one of the original directors, and a former chairman of the Company, Mr. W. F. Orris, the promoter of the Company, and other witnesses having been examined, the inquiry was closed.

Liège.—A concession is offered at Liège by the Administration Communale for the construction and working of a central station in that town for twenty-five years, the town having the option of purchasing the undertaking at certain intermediate periods. At the expiration of the concession the whole of the concern passes into the possession of the town without any payment whatever. Particulars may be obtained of the Administration Communale, Liège, Belgium.

Seel Glow Lamp Co. (Berlin).—The falling off in prices and the competition of the incandescent gas light, have, according to the Directors of this Company, rendered the manufacture of this type of lamp unremunerative, and it has been resolved to liquidate the Company.

Aberdeen.—A motion to instruct the Docks and Pilotage Committee to report as to the propriety of lighting the harbour quays by electricity was discussed at the Harbour Board at its last meeting, but an amendment to the contrary was approved.

Barrow.—The Barrow County Council have referred to a Committee the question of the advisability of applying for an Electric Lighting Provisional Order.

Baths Lighting.—The St. Marylebone Baths Commissioners propose making extensive alterations which will probably include the laying down of an electric-lighting plant.——A proposal to light the public baths of Paddington is also under consideration by the Commissioners.

Bedford.—A proposal has been made to the Sanitary Authority by Mr. F. H. Medhurst, electrical engineer, Cambridge, asking permission to negotiate and settle the terms of the transfer of the Electric Lighting Order to a company to be formed by that gentleman for carrying out the works and obligations of the Order. Mr. Medhurst proposes that the company should refund to the Corporation any sum up to £500, which had been expended in obtaining the Order, and suggests that the high-tension alternating current transformer sub-station system should be adopted. It was proposed to discuss the proposal in a committee of the whole Council, and to call a public meeting on the subject of electric lighting generally.

Belfast.—After reading and discussing the report of Prof. Kennedy, the Belfast Corporation instructed the Town Clerk to write for further information upon certain details of Prof. Kennedy's scheme.

Bideford.—Mr. Coham, of St. Austell, Cornwall, is engaged in preparing plans and estimates for lighting the centre of the principal establishments in the town of Bideford, including the Royal Hotel.

Blackpool.—A resolution of the Electric Lighting and Tramways Committee of the Town Council that the charge for electrical energy for incandescent and alternate-current arc lights shall be fixed at 6d. per unit, subject to discounts varying from 5 to 25 per cent., and that the rentals for meters, transformers, and other apparatus provided by the Corporation shall be fixed at from 7s. 6d. to £1. 5s. per quarter for installations of from 1 to 25 c.p. lamps to 300 8 c.p., and for larger installations by special arrangement, was, owing to the absence of the Chairman or the Committee, sent back for reconsideration, it being the opinion of several members of the Board that the discounts allowed to large consumers was too great.

Bowness and Windermere.—It has now been finally decided by the Local Boards of Bowness and Windermere to adopt the electric lighting scheme, about which there has been some friction between the two local bodies. A clause has been added to the agreement, that if either of the Boards decline to enter into the arrangement for purchase the other Board should be at liberty to negotiate alone.

Braintree.—A discussion upon the subject of providing steam-power for the purposes of electric lighting at the last meeting of the Local Board, was summarily cut short by the Chairman stating that

Hosted by Google

the town was not likely to go in for electric lighting just at present, and that, therefore, he did not feel particularly interested in the matter. A little healthy agitation on the subject evidently would not be out of place in this district, several members of the Board being in favour of the adoption of the electric light.

BUCKINGHAM.—The tender of Messrs. Parr and Gillies for supplying bracket lamps and lighting the entrances to the Town Hall and Post Office at 25s. per lamp per annum has been accepted ; this charge to include renewals.

CARDIFF.—The *South Wales Daily News* of the 9th inst. contains an account of an interview with Mr. W. H. Massey on the subject of the utilisation of water-power for the Cardiff lighting scheme.

CHESTERFIELD.—An expert is to be engaged to advise the Electric Lighting Committee on the subject of lighting the town by electricity.

CHURCH LIGHTING.—The first church to be lighted by electricity at Glasgow is Free St. Paul's. Lamps varying in candle-power from 16 to 200 are used. In the pulpit a switch is placed, so that the minister can turn on the pulpit lamps when required. The work is being carried out by Messrs. A. MacLellan and Co.

DERBY.—Some months since it was determined by the Directors of the Midland Railway Company that the electric light should be established in the new offices which were at that time being built for the engineer of the line and the general manager's department, as also in all other offices where clerks were required to work late at night. The main object of the Directors was to secure hygienic advantages for the large staff employed at Derby. Every effort was made to bring the lighting into operation shortly after the autumn of last year, but it has only recently been started. The lighting authorised consists of about 2,000 16-c.p. lamps, distributed through what may be called the station offices proper, the engineer's department, accountant's, goods offices, and mineral offices. It is also intended to light the Railway Literary Institute, a building now under construction, and which is to take the place of the old Literary Institute, absorbed in other alterations now being carried out. As even this amount of lighting does not light the whole of the Company's offices, an extension of about 1,500 lights will ultimately be required. Some difficulty has been found in selecting a suitable site for the generating station, the area over which the lighting had to be carried being of a rather widely extended character. A site has been selected some short distance from the Derby Station itself, fairly situated for reaching the many outlying points required to be served, and from which a network of cables has been laid with ample flush-box accommodation. Cables are carried direct to the distribution board in the engine house, so that there are but very few, if any, joints throughout the system. The "three-wire" system of distribution is employed, but arrangements are made for forming this into the ordinary two-wire parallel system during light loads, when one engine and dynamo is sufficient. The generating station is a well-arranged building, with boiler house, engine and dynamo room, office, store room, and workshop. The two boilers at present laid down are of the locomotive type ; the engines are supplied by Messrs. Willans and Robinson, coupled to Siemens (simple shunt) dynamos (two of 500 amperes at 120 volts, and one of 275 amperes), the latter being for the light loads, the two others for the heavier loads. A special switch has been designed by Mr. Sayers, a member of Mr. Langton's (the Company's telegraph engineer) staff, the object of which is to prevent any inconvenience in turning over from the two to the three-wire system, or *vice versâ*. The dynamo room possesses a fine switchboard, fitted with special switches, Lord Kelvin's ampere meters, distribution boards, and safety fuses. About 1,000 lights have already been brought into use, and the remainder will follow immediately.

EDINBURGH.—On Tuesday the Edinburgh Town Council decided that the report presented by Prof. Kennedy on the subject of the electric lighting of the district should be printed and distributed. There is little difference in the cost of the various schemes suggested, the estimated amount being about £85,000. Prof. Kennedy discusses the question of low and high-tension in his report, which, we understand, includes recommendations for the adoption of both systems in certain conditions.

FALKIRK.—The Hospital Committee of the Town Council recommend the establishment of telephonic communication between the Burgh buildings and the hospital, and the Council's inspector has been instructed to prepare a report on the subject of lighting the hospital electrically.

FALMOUTH.—A report has recently been presented to the Falmouth Urban Sanitary Authority, recommending the adoption of public electric lighting at an annual cost of not exceeding £650.

FOLKESTONE.—The Town Council will again consider the question of lighting the town by electricity.

GLASGOW.—At a meeting of the Glasgow Lunacy Board last week an important discussion arose on the question of the introduction of the electric light at the Board's Asylum at Gartloch. It was estimated that a total number of 1,300 lights would be required, and Messrs. Mavor and Coulson had supplied the Board with a report upon the subject, estimating that the cost of plant, exclusive of building, would be about £7,000 and the annual expense about £840, and further estimated that a saving of £86 per annum would be effected over this estimate by the use of oil gas. A discussion ensued, and it was finally agreed that the minutes of the Lighting Sub-Committee be taken and schedules issued to electric-lighting and gas-oil companies asking for estimates of plant and working expenses for lighting and heating ; the schedules to be submitted to a subsequent meeting of the Board. There seems every probability that, ultimately, the advantages of the electric light will prevail.

GRIMSBY.—The cost of the electric lighting installation for the new council chamber and banquet room will be about £1,200.

HACKNEY, LONDON, N.E.—The Board of Works for this district have finally decided upon applying to the Board of Trade for a Provisional Order to enable them to supply electric light and power for the district.

HENLEY.—The Electric Lighting Committee of the Town Council have received an offer from Mr. W. H. Massey to provide them gratis with certain information in regard to the electric lighting of the district. Mr. Massey is a resident in the neighbourhood.

HOVE (SUSSEX).—The Town Hall Committee have still under consideration the designs and offers sent in for wiring, fitting, and preparing the Town Hall for lighting by electricity

HYTHE.—The Hythe Tramway has been disposed of, and will be worked by electricity.

KINGSTON.—A public meeting has been held to consider the proposal of the Corporation to spend £16,000 on electric lighting. A motion that the meeting approve of the Corporation's action in the matter was ultimately carried by a very large majority.

LECTURES.—Prof. Fitzgerald lectured last week in Dublin on Tesla's experiments. He took occasion to point out that Ireland stood in need of endowment for scientific research.

LLANGOLLEN.—Mr. Davies, at the last meeting of the Local Board, obtained leave to defer the introduction of the electric light into the town for a month.

OSWESTRY.—A communication from the newly-formed Oswestry Electric Lighting Company (Limited), notifying the Local Board that they were about to apply for a Provisional Order for lighting the district, has been referred to the General Purposes Committee.

PORTRUSH.—At the last meeting of the Town Commissioners a lengthy discussion arose upon the proposal to light the town by electricity, and it was ultimately decided that the Commissioners should subscribe privately the amount required for a survey by a competent engineer, and his estimate as to the probable cost.

RUGBY.—The mansion of Mr. A. H. E. Wood, at Newbold Revell, Rugby, is being equipped with an electric lighting plant of considerable extent, which consists of two Cornish boilers and two combined sets of engines and dynamos of the Parsons steam-turbine type, indicating 50 H.P. and capable of running 500 incandescents, and accumulators estimated to supply 350 16 c.p. lamps. About 560 lamps are included in the installation, from 8 to 50 c.p., making a total of 7,800 c.p. in all. The current is to be supplied to the mansion, stables, laundry, fire-engine house, kennels, swimming bath, gymnasium, racquet court, &c. ; and the machinery in the refrigerator house is to be driven by a 1½ H.P. electric motor. The installation is under the supervision of Mr. A. A. Campbell Swinton, and is on the lines of the plant completed for the Earl of Durham at Lambton Castle.

SOUTHEND.—At the last meeting of the Town Council it was resolved to borrow £4,000 for providing further electrical plant and cars for the Southend Pier.

WESTON-SUPER-MARE.—The result of the correspondence between the Brush Company and the Town Commissioners is that the Commissioners have notified the Company that they are prepared to consider a proposal for the transfer of the Commissioners' Provisional Order to a local company, to be formed by the Brush Company ; but any proposition for payment for goodwill on the expiration of the term fixed will not be entertained.

YARMOUTH.—A proposal of the Electric Lighting Committee adopting a scheme which it is estimated will entail an expense of £15,000, came up for discussion at the last meeting of the Town Council, and was agreed to. Mr. Preece is to be asked to accept the position of consulting engineer under the scheme, and the authorities are applying to the Local Government Board for a loan of £15,000.

COMPANIES' MEETINGS & REPORTS.

Birmingham Electric Supply Company (Limited).

The third annual meeting of the Birmingham Electric Supply Company (Limited) was held on Thursday at the offices, Dale End, Birmingham, Mr. H. Buckley in the chair.

The CHAIRMAN, in moving the adoption of the annual report (which appeared in *The Electrician* of March 3rd), said that the Company had made slow but steady and satisfactory progress. The number of lamps supplied at the close of 1891 was 5,480, and at the close of 1892 the number was 8,329, the average for the whole of last year having been 6,830, as compared with 3,135 for the nine months preceding. The number of consumers increased during last year from 133 to 223, and was still increasing. It was satisfactory to note the increasing demand for the arc light, showing that consumers were fully alive to the fact that no light was more economical, not even the city gas. The Company's cost of production compared favourably with that of any other company in England, but it was a matter of regret that in contracts for fittings the margin of profit was so small. Last year the profit under that head amounted to £260. In the majority of cases the Company could not attempt to do work at the prices at which other contractors under the pressure of competition were prepared to it. Since the last annual meeting they had issued the whole of the remaining share capital, and the Company was now in the satisfactory position of having its entire share capital placed, and being entirely unfettered by Preference shares or debentures, a state of affairs that was rather unusual with electric supply companies in the United Kingdom. The Directors proposed to add to the depreciation reserve fund £1,279, bringing that fund to £1,636. This was considered ample for the time the Company had been in existence. Before recommending the payment of a dividend, the Directors thought it wise, in view of the existence on the other side of the balance-sheet of the item of £1,685 preliminary expenses, that something should be done towards creating a general reserve fund. They therefore proposed to carry £250 of the year's profits to that fund, and to declare a dividend of 3½ per cent. This dividend, he thought, would be considered satisfactory by the shareholders, considering the time the Company had been at work. It was rather astonishing to him that some of their large banks and other establishments had not yet adopted the light, to the advantages of which the proprietors seemed to be fully alive. The chairman of one of the largest banks in Birmingham remarked that he did not hesitate to say that the entire cost of the change would be saved to the bank in the improved health of the staff. In reference to the proposed extension to Edgbaston and the jewellers' quarter, the Company had been treated, as it always had been, with the greatest courtesy by the Corporation, but in view of the attitude of the Committee to which the matter was referred, they had abandoned the intention to apply for increased powers this session. The Company, however, would bring the matter forward again as soon as possible, and would press its claim upon the Corporation, unless the Coporation decided to supply those districts itself.

Mr. C. A. HARRISON seconded the motion, which was carried unanimously.

The retiring Directors (Messrs. G. S. Albright and Mitchell) and the auditors (Messrs. Sharp, Parsons, and Co.) having been re-elected, the meeting closed in the usual manner.

City of Bath Electric Lighting and Engineering Company (Limited).

The second annual meeting of the shareholders of this Company was held at the works in Dorchester-street, on Saturday, Mr. Emile Garcke, Chairman of the Company, presiding.

The annual report of the Directors, which was taken as read, was as follows:—

"The business of the Company has steadily increased during the past year, the number of lamps now connected being 6,420, as against about 5,000 at the end of 1891, and the receipts from current sold to private consumers have amounted to £2,129. 14s. 4d., as compared with £1,295. 13s. 7d. for the previous year. Notwithstanding, however, this large increase in the amount of current sold, the result shown by the profit and loss account is a loss of £300. This unsatisfactory result is due to a large number of the consumers still being charged on the rental system instead of by meters, so that the all-day supply which the Company is now giving has led to an increased expenditure, which is out of all proportion to the increase of revenue. The rental system was introduced before the Company took over the business, and before the all-day supply was given. The Directors are now, however, terminating these arrangements as quickly as is practicable, and they firmly believe that the customers as well as the Company will benefit by the adoption of meters. Some of the customers, who have already adopted meters, have, as a result of greater economony in the use of the light reduced their bills below the former contract amounts. This is an advantage to the Company, because it is better that the customers should consume less current and pay for all they have than that they should unnecessarily consume a larger amount of light for which, under the rental system, the Company is not paid. The electrical and other plant of the Company has been kept in thorough repair and perfect working order, and the several improvements affected in the station during the year have placed the Company in a satisfactory position for dealing with the increased demand for light. The Directors have during the year issued £800 debentures bearing interest at the rate of 4½ per cent., part of the total issue of £3,000. The Directors have in view of the loss waived their fees for the past year. The auditor retires and offers himself for re-election."

The CHAIRMAN referred to the retirement of Colonel Vaughton from the chair and to the many services he had rendered to the Company. He commented with satisfaction on the large increase in the receipts of the Company compared with the previous year, and pointed out that the loss referred to in the accounts had been caused by the unlimited use of the current by those who still had it on the rental system. The meter system, however, which they were introducing, tended to induce the customer to economise, and would greatly improve matters. With regard to the balance-sheet, they had expended £4,838. 17s. 2d. on increasing the mains and apparatus, a general extension of the system enabling them to supply a larger number of customers. This expenditure had been met by raising a mortgage on the premises, and by issuing some debentures at a moderate rate of interest to the extent of £3,800. He did not think the balance-sheet called for any other comment on his part, but he would be happy to give any information that was required. He pointed out that in view of the loss in question the Directors had declined to take any fees. For two and a-half years the Directors had taken no remuneration whatever, and they had also enjoyed the time and services of Mr. Massingham, the Managing Director, without any remuneration other than what he obtained as a shareholder. The plant, the mains, and the apparatus by which they carried on their business generally, were in a very satisfactory condition. They had taken pains during the year, not only to maintain the efficiency of the entire system, but they had spent some money in addition to the figures appearing in the capital account on the ordinary working of the business which was fairly chargeable to the capital account, or rather to the maintenance of the plant. He had also to inform them that the plant had not only been ample for the present lighting requirements, but left them a very satisfactory margin for extensions, and they were thus prepared to carry on a much larger business than they did at present without very materially increasing the capital account. He concluded by formally moving the adoption of the report of the Directors and the accounts.

Mr. GARRETT seconded the motion, which was carried after a short discussion, and the auditor having been re-elected, the meeting terminated.

Scarborough Electric Supply Company (Limited).

The first statutory meeting of the shareholders of this Company was held on Friday at the offices, 102, Westborough, Scarborough, Lieut.-Colonel R. F. Steble presiding.

The CHAIRMAN said that the meeting was a formal one, being the statutory meeting they were obliged to hold within four months from the date of the registration of the Company, and he did not intend to do more than explain what had been already done in connection with the formation of the Company and the construction of the works. In the first instance the Corporation had the power to bring electric light into the town, but they came to the conclusion that it would be wiser to let a private company introduce it and supply it for a term of years, as they (the Corporation) would have the power to purchase at the expiration of that time. A concession was thereupon granted to Mr. Campbell Swinton, and he set about at once to form a Company to carry out the order he had obtained from the Board of Trade. The Company was formed with a nominal capital of £50,000, and the Directors then ascertained what the cost of starting the works would be. It was estimated that they would entail an expenditure of £20,000, and they then determined to make an issue of shares up to £20,000. They had not the slightest difficulty in realising that sum of money, and he was now going to make a suggestion, with which, he believed, the other Directors would agree, that they should increase the capital still further, not for the purpose of calling it up all at once, but in order to relieve those who had already subscribed, and to enable them to extend the works without going cap in hand for the money, and paying an enormous price for it. The Chairman then referred to the central station in course of erection, which could be extended to provide 100,000 lights, if necessary, and said that he looked with great hope on the prospects of the Company.

Mr. A. A. CAMPBELL SWINTON (the Managing Director and Consulting Engineer) reported that the generating plant that had been ordered would consist of two independent sets of engine and dynamo each set being of about 200 H.P., and capable of supplying 150 electrica units. The engines are of the Parsons steam turbine type, and drive the dynamos direct at a speed of about 5,000 revolutions per minute, or about 80 per second. Steam would be supplied to the engines at 120lb. steam-pressure by two Lancashire boilers, each 28ft. long by 7ft. 6in. in diameter The supply station would be furnished with the usual complement of subsidiary machinery, consisting of two feed-pumps, travelling over head crane, switching apparatus, measuring and regulating apparatus &c., all of a very complete description. The capacity of the machinery now arranged for and ordered is 300 units, or about 400 H.P. sufficient to supply about 7,000 lamps ; the buildings are, however, being built with a view to ultimate requirements. It was proposed, in the first instance, to lay down about 4½ miles of mains, which would cover the chief business and residential quarters of the town and thereafter extensions can be made as the demand arises. The mains will consist of highly-insulated cables drawn into cast-iron pipes, and laid under the footways, with junction boxes about every 50 yards. Referring to Newcastle-on-Tyne and Cambridge, where similar machinery, &c., are used as proposed at Scarborough, he pointed out that at the latter place the Company was making a good profit, and the former paid last year a 5 per cent. dividend, and this year 5½ per cent. The Company have power to charge 7d. per unit, which is equivalent to a farthing per hour for an 8-candle-power lamp. For large consumers, however, it is proposed to make a considerable rebate, amounting to 25 per cent. to those who have a large number of lamps and burn them for long hours.

Hosted by Google

The retiring Directors, the ex-Mayor (Lieut.-Colonel Steble), Mr. J. W. Woodall, J.P., and the Mayor (Mr. John Dale) were re-elected, and Mr. C. E. Bradley was appointed auditor.

Mr. F. BRIGHT asked if there was any period specified when the works would be completed.

The CHAIRMAN stated that they expected the works would be completed early in July.

A vote of thanks having been passed to the Chairman, the meeting terminated.

Elmore's Patent Copper Depositing Company (Limited).

An extraordinary general meeting of this Company was held yesterday at the Cannon-street Hotel to consider the steps to be taken with a view to raising additional working capital for the purposes of the Company.

Mr. J. J. ATKINSON, who presided, said that he was pleased to state most positively that the Elmore process was perfectly successful as a manufacturing operation. In corroboration of that he could point to the French Elmore Company's undoubted industrial success, and they were informed that the expert who recently visited the French works on behalf of an influential body of their shareholders had reported to his principals most favourably in regard to the industrial position and prospects of that Company. It was the unanimous declaration of the Directors that the Elmore process was perfectly sound, and could be worked remuneratively. The present capacity of their works was for an output of from 15 to 20 tons per week, and they had a considerable number of orders in hand in course of execution, and would have no difficulty whatever in obtaining orders for steam pipes sufficient to occupy the whole of their plant. The one and only barrier to taking those orders and earning a dividend was the fact that they lacked the necessary working capital. They had experienced the want of an adequate supply of raw copper for many months, and that fact would account for the smallness of their output. The finished output, as taken from the actual working books at Leeds, from June 30, 1892, the date at which the last balance sheet was issued, up to February 25, was 102 tons. The actual manufacturing expenses of that output, exclusive of the administration charges and interest, were £3,396, an average cost of 3·57d. per lb. They had sold in the same period, 50 tons of stuff, 38 tons of which were tubes and ram work, and 12 tons scrap copper. The net invoice value to the customers from the 38 tons was 11·7d. per lb.; and as the gross cost of producing that was 8·5d. per lb., they were left with a profit of 3·2d. per lb. The trading liabilities of the Company were comparatively small and were more than set off by book debts and the raw and manufactured copper in stock. The Directors suggested that the 8,800 shares in hand should be issued as Six per Cent. Preference Shares. The Board also thought that the interests of the Company would be served by the appointment of a strong representative committee who should co-operate with the Board. They believed the £17,200 proposed to be raised by means of Preference Shares would supply all the money required to enable the business to be made a success.

In reply to Mr. Freeman,

Mr. WILLIAM ELMORE said that, although the Chairman of the Company and himself had at different times made various statements, they were prepared to prove the truth of their statements to the Committee of Investigation. The pan licence was still in existence, and would as soon as matters improved be carried out. It was perfectly untrue to say that his sons and himself had made large sums of money out of the Company.

A SHAREHOLDER suggested that a statement should be sent to the shareholders, showing the amount of capital originally subscribed, the amount since obtained on mortgage, and the manner in which those sums had been expended.

Mr. HAYS proposed the appointment of a Committee of seven shareholders to investigate the affairs of the Company and to report to a future meeting.

The motion was seconded and agreed to.

Elmore's Wire Manufacturing Company (Limited).

An extraordinary general meeting of this Company was held yesterday, at the Cannon-street Hotel, to consider the steps to be taken with a view to raising additional capital for the purposes of the Company.

Mr. J. J. ATKINSON presided, and said the shareholders were not asked to bolster up a defeated process, but to take advantage of a complete success. The Company owed £11,000 and interest to its bankers, and there were sundry creditors amounting to £9,000 in all. The subscriptions to the debenture issue had up to the present amounted to only £9,000, but he thought the Company would be able to obtain £20,000 from a financial institution by giving a first charge upon the property, provided the shareholders would subscribe a further £20,000 to be secured by a mortgage debenture ranking immediately after the first-mentioned debenture.

As in the case of the Elmore's Copper Company, it was thought necessary to appoint a Committee of Investigation.

In the course of the discussion which followed a committee was unanimously appointed.

Direct Spanish Telegraph Company (Limited).

The following is the report and accounts of the Directors of this Company for the half-year ended December 31st last, to be presented at the general meeting of shareholders, to be held on Friday, the 24th inst., at Winchester House, E.C., at 12 o'clock :—

The accounts show, after providing for debenture interest, a balance to the credit of profit and loss, of £5,438. 19s. 7d. The traffic receipts show an increase of £30. 14s. 7d. as compared with the corresponding period of 1891. The working expenses are £56. 9s. 9d. in excess of those for the corresponding period of last year.

The Company's cables, and the land-lines in connection with them, have continued in good working order throughout the half-year.

The Directors, with a view to strengthen the good relations existing between the Company and their staff, propose to follow the practice adopted by many companies, in assisting their *employés* to make provision for their old age, or for their representatives after death. Arrangements have been made for taking out endowment policies on which, under certain conditions, the Company pay one-half of the premiums. It is calculated that the amount which the Company can be called upon to contribute will not exceed £250 per annum.

After adding the usual sum of £2,500 to the reserve fund, the balance of profit and loss amounts to £2,938. 19s. 7d. Out of this amount the Directors recommend the payment of the dividend at the rate of 10 per cent. per annum on the Preference shares, and a dividend at the rate of 4 per cent. per annum (free of income-tax) on the Ordinary shares. There will then remain a balance of £442, which will be transferred to the reserve fund in part repayment of the balance of £1,935. 9s. 4d. still remaining due to that fund for the repairs of the Falmouth-Bilbao cable in November, 1891. The reserve fund now amounts to £33,273. 15s. 2d.

Mr. E. Etlinger and Mr. J. Denison Pender are the Directors retiring by rotation, and offer themselves for re-election. The auditor, Mr. Herbert R. Duke, retires, and offers himself for re-election.

NEW COMPANIES, STATUTORY RETURNS, &c.

AMERICAN RIVER ELECTRIC POWER SUPPLY COMPANY (LIMITED).—This Company was registered on February 28th with a capital of £25,000, in £1 shares, to carry into effect a certain agreement between the American River Syndicate (Limited), William Smith, and Henry Ward, of 6, Queen-street-place, London, E.C., to erect central stations for the generation, production, storage, and supply of electricity, electrical motive power, or similar agency, for lighting, heating, and motive purposes, in California and elsewhere; and to supply or use the same for the production, transmission, or use of power for lighting, heating, signalling, telegraphic, telephonic, and motive or other purposes; and to carry on the business of electricians, electrical, and mechanical engineers, suppliers of electricity and manufacturers of electrical and scientific apparatus. The first Directors are Viscount Grimston, Francis Retallack, Commander Oliver Young, R.N., John Taylor, M.Inst.C.E., and George C. Pearson.

ARIEL COMPANY (LIMITED).—This Company has been registered with a capital of £15,000, divided into 1,000 Preference and 2,000 Ordinary shares of £5 each, to acquire certain patents, patent rights, trade marks, &c., and to carry on the business of electricians, mechanical and electrical engineers, general contractors, manufacturers of engines, machinery, and apparatus, suppliers of electricity, and workers and dealers in electricity for the purposes of locomotion, light, and heat, and any business in which the application of electricity or other power is, or may be, useful, convenient, or ornamental. The subscribers include E. D. Purbright, civil engineer; H. F. Jackson, electrical engineer; F. C. Nunn, civil engineer; and G. Aken, electrician; all with one share each.

ELECTRIC ANTI-CORROSION COMPANY (LIMITED).—This Company has been registered with a capital of £6,000 in £10 shares, to purchase an invention for which a Provisional Protection has been granted, No. 6,105 (1892), a French patent, No. 223,664 (1892), and an Italian patent No. 472 (1892), or any improvements therein, and to enter into and carry into effect an agreement made between John Telfefsen, James Bennett, and Albert C. Woodford (as agent for the Company).

ELECTRIC SEMAPHORE SIGNAL SYNDICATE (LIMITED).—This Company was registered on March 9 with a capital of £3,000 in £1 shares, to carry on the business of electrical and mechanical engineers, electricians, suppliers of electricity for the purposes of light, heat, motive power, or otherwise, and manufacturers of, and dealers in, all kinds of electrical and scientific apparatus.

ELECTROLYTIC SEPARATION SYNDICATE (LIMITED).—This Company was registered on the 11th inst. with a capital of £25,000, in £1 shares, to acquire the patent and other rights of Claude T. J. Vautin for and in respect of an invention for "improvements in the method of, and apparatus for, the electrolytical separation of the bases of salts and compounds of the same from saline solutions, and with a view thereto to adopt and carry into effect an agreement to be made between Claude T. J. Vautin of the one part, and James Thame (for the Company) of the other part."

THOMAS HOLT (LIMITED).—Registered with a capital of £10,000, in £5 shares, to carry on business as machinists, mechanical and electrical engineers, tool makers, iron and brass founders, fitters, machinists, &c.

ISLES (LIMITED).—Capital £20,000 in £10 shares, to carry on the business of brass and iron founders, mechanical and electrical engineers, crane makers, at Stanningley, Yorks.

JONES' PATENT STEEL COMPANY (LIMITED).—Capital £10,000 in £5 shares. Metal workers, metallurgists, brass and iron founders, smelters, mechanical and electrical engineers, &c.

R. A. LISTER AND CO. (LIMITED).—This Company was registered on the 13th inst., with a capital of £20,000 in £20 shares, to carry on the business of brass and iron founder and mechanical and electrical engineer, carried on by Robert A. Lister.

Hosted by Google

HERCULITE MANUFACTURING COMPANY (LIMITED) (in Liquidation).—A meeting is to be held at 5, Crooked-lane, E.C., on March 27th, at 11, to receive an account of the winding-up.

KENSINGTON AND KNIGHTSBRIDGE ELECTRIC LIGHTING COMPANY (LIMITED).—The annual return of this Company, made up to March 2nd, has been filed. The nominal capital of the Company is £350,000, divided into 50,000 ordinary, 10,000 First Preference, and 10,000 Second Preference Shares, all of £5 each; 15,000 Ordinary and 10,000 First Preference Shares have been taken up, and the full amount called. The calls paid amount to £100,000, while shares to the value of £25,000 have been issued as fully-paid.

KINGSTON-UPON-HULL ELECTRIC LIGHTING AND SUPPLY COMPANY (LIMITED).—This Company has been dissolved. The Company was registered in June, 1889, with a capital of £1,000 in £1 shares, to carry on the business of an electric light, heat, and power supply company. No capital was ever raised.

LEICESTER ELECTRIC LIGHT AND POWER COMPANY (LIMITED).—This Company has been dissolved. The Company was registered in June, 1889, with a capital of £1,000, in £10 shares, to supply electricity in Leicester and neighbourhood.

MOUNTAIN'S WIRE MANUFACTURING COMPANY (LIMITED).—On the petition of Messrs. Leatham, Few and Co., Mr. Justice Vaughan Williams on Saturday ordered this Company to be wound up.

NEWCASTLE AND DISTRICT ELECTRIC LIGHTING COMPANY (LIMITED).—The annual return of this Company, made up to February 27, 1893, has been filed. 3,535 shares out of a total capital of £50,000 in £10 shares have been taken up, and a call of £8 per share made. The calls paid amount to £28,040, leaving £240 in arrears.

UNITED ELECTRICAL ENGINEERING COMPANY (LIMITED) (in Liquidation).—A meeting is to be held at A. S. Gedge's, 3, Great James-street, Bedford-row, on April 5th, at 12, to receive an account of the winding-up.

UNITED ELECTRIC SEWAGE AND CHEMICAL SYNDICATE (LIMITED).—The statutory return of this Company, made up to December 19, 1892, has been filed. Out of a capital of £5,000, in £1 shares, 4,757 shares have been taken up, of which 4,750 have been issued as fully paid, £7 being paid on the remaining shares.

WENHAM COMPANY (LIMITED).—The annual return of this Company, made up to December 30, 1892, has been filed. The Company was registered in May, 1888, with a capital of £250,000, in £1 shares, to carry on the business of mechanical, gas, and electrical engineers, &c. In 1889 the Company resolved to reduce its capital to £83,333. 6s. 8d., divided into 250,000 shares of 6s. 8d. each, which reduction was subsequently confirmed. At the time of making up 178,954 shares were taken up, of which 7 were taken by the signatories to the Memorandum of Association, the remainder being issued as fully paid.

WEYBRIDGE ELECTRIC SUPPLY COMPANY (LIMITED).—The annual return of this Company, made up to January 12th, shows that only seven shares have been taken up out of a capital of £15,000 in £5 shares, no calls having been made.

WOLVERHAMPTON ELECTRIC LIGHT AND POWER COMPANY (LIMITED).—The annual return of this Company, made up to February 15, 1893, discloses the fact that the 23 original signatories are the only shareholders. They took one share each, and have paid the full amount of £10 per share thereon. The nominal capital is £50,000, in £10 shares.

WOOLWICH DISTRICT ELECTRIC LIGHT COMPANY (LIMITED).—The annual return of this Company, made up to February 25th, has been filed. The nominal capital is £10,000, in £1 shares, and 3,435 of these shares have been taken up. 150 shares have been issued as fully paid, and upon 265 shares the full amounts have been called, upon 2,900 shares 7s. 6d. per share has been called, upon 25 shares 10s. per share has been called, upon 75 shares 5s. per share has been called, and upon the remaining 20 shares no calls have as yet been made. The calls paid amount to £1,383. 15s.

WREXHAM AND DISTRICT ELECTRIC SUPPLY COMPANY (LIMITED).—The usual return made up to and filed on February 20, 1893, shows that this Company has made no progress since last return. The Company was incorporated in 1889, with a capital of £20,000, in £5 shares, and but 115 shares have been taken upon, no calls having been made. The gentlemen who signed the Memorandum of Association are the only shareholders.

CITY NOTES, &c.

CITY AND SOUTH LONDON RAILWAY COMPANY (LIMITED).—The traffic receipts for the week ended March 12th were £859, as against £876 for the corresponding period of last year, being a decrease of £17. The total receipts for half-year amount to £9,531 against £8,508 in the corresponding period of 1892, being an increase of £1,023.

CONSOLIDATED TELEPHONE CONSTRUCTION AND MAINTENANCE COMPANY (LIMITED).—Notice is given that an extraordinary general meeting of the members of this Company will be held at Winchester House, E.C., on Tuesday, March 28th, at 12 o'clock, when the resolution passed at the last extraordinary general meeting on Thursday, the 9th instant, will be submitted for confirmation as a special resolution.

MEXICAN TRAMWAYS.—It is stated that an English syndicate is negotiating for the whole of the tramway companies in the city of Mexico.

ROCKHAMPTON (QUEENSLAND) GAS AND COKE COMPANY (LIMITED).—The Directors' report for the half-year ended December 31, 1892, presented at the meeting held on the 10th ult., after alluding to their being able to place a satisfactory report before the shareholders, dealt as follows with their electric-lighting scheme:—"The commencement of the electric-lighting operations was a step taken to protect the Company, and to retain the power conferred upon it by the special Act of Parliament. Owing to the want of additional capital the work of completing the private installations had to be suspended, and the electric-light station has consequently been placed under the great disadvantage of running to supply merely twelve consumers. No time will be lost in finishing the various business places which are waiting for the light. As they become gradually wired up and the full capacity of the machinery utilised, so will the revenue be sufficient for the payment of the working expenses and interest, and the Directors feel sanguine of the future maintenance of the usual dividend. No definite arrangement has yet been made with the Municipal Council for the lighting of the streets with the powerful arc-lamps. The Company submitted a price which is now under consideration. The loss sustained upon the electrical operations is £595. 3s. 1d., which includes £365. 14s. 5d. charged for interest upon the capital involved, together with legal expenses, printing, &c. As there are many things included in this loss inseparable from the starting of a new undertaking such as this, the Directors consider that at least a part of this should be borne by the reserve fund, and they have, therefore, decided to appropriate £250 of this fund towards the payment of the half-year's dividend, at the same time charging the whole loss to the profit and loss account for the past half-year." The Directors recommended the payment of a dividend at the rate of 10 per cent. per annum.

WESTERN AND BRAZILIAN TELEGRAPH COMPANY (LIMITED).—The traffic receipts for the week ended March 10, 1893, after deducting 17 per cent. of the gross receipts payable to the London Platino-Brazilian Telegraph Company (Limited), were £3,484.

WOODHOUSE AND RAWSON UNITED (LIMITED).—On Saturday last the *Financial Times* contained the announcement that a receiver had been appointed in this matter, an occurence which was not altogether unexpected by those acquainted with the position of affairs. The following circular has been sent out by the Directors to the shareholders:—

"Woodhouse and Rawson United (Limited),

"88, Queen Victoria-street, London, E.C., March 9, 1893.

"Notice is hereby given that an extraordinary general meeting of the above Company will be held at the Cannon-street Hotel, in the City of London, at 12 o'clock noon, on Monday, the 20th day of March, 1893, for the purpose of considering and, if thought fit, of passing as an extraordinary resolution the following resolution—that is to say,

"'That it has been proved to the satisfaction of this meeting that the Company cannot, by reason of its liabilities, continue its business, and that it is advisable to wind up the same, and accordingly that the Company be wound up voluntarily, and that there be conferred on the liquidator or liquidators all the powers which, by virtue of the Companies' Acts, 1862 to 1890, can be conferred on Liquidators.'

"Should the resolution be passed a further resolution will be proposed at the same meeting for the appointment of a liquidator or liquidators for the purposes of such winding-up.

"Should these resolutions be passed, the Directors propose to submit to the meeting, at all events for preliminary discussion, the scheme for the future reconstruction of the Company."

Accompanying this circular was a letter, signed by the Assistant-Secretary, conveying the Directors' opinion that the constitution of the Company can only be modified by a scheme of reconstruction, and that the resolution to be proposed at the meeting for winding up is merely part of the legal machinery required for effecting what is desired. The Directors prepare the shareholders for the appointment of a receiver and manager on behalf of debenture-holders by stating that they are not prepared to oppose the appointment of such a person. We understand that the shareholders in this concern have also received copies of the report of the Investigation Committee with the Directors' observations marked against the various statements and comments of that Committee. The full report of the Investigation Committee appeared in the last issue of *The Electrician*, and in reference to the various clauses the Directors observe that they offered the Committee every facility for pursuing their inquiries. With regard to the £75,000 guarantee fund, concerning which, it will be remembered, the Committee of Investigation expressed themselves strongly, the Directors state that this fund was available for use in the Company's business, and on the date of the authorisation for its return was not represented by cash in hand, and, had no arrangement been made the whole of the £75,000 might have had to be paid in cash, involving a realisation of shares and securities at much sacrifice. The Directors demur to the opinion expressed by the Committee that the profits for the first year consisted of very doubtful items, and, taking the transactions with the Kensington Stores, the International Okonite Company, and Jensen's Bell, they consider these items were all of the full commercial value set against them in the balance-sheet, and, more particularly in reference to the Okonite Company's shares, the Directors claim that "a regular income of over £1,400 per annum is received." The £24,000 debentures in the Okonite Company are, in the Director's opinion, worth par. With regard to the large sum of £13,775 commission to the Managing Director, the Directors state that this gentleman never received any portion of this amount in cash, but took the amount in shares of the Company in order to enable it to obtain a quotation on the Stock Exchange. It will be seen that the Directors here contradict the statement made by the Committee that Mr. F. L. Rawson received £10,000 in cash out of this commission sum. The Directors state that the Company acquired a large interest in the Epstein patents, and are satisfied that the Epstein shares and advance will realise full value. The remainder of the Directors' observations is a general depreciation of the Committee's

Hosted by Google

conclusions, the final comment being that the Preference and Ordinary shares in Woodhouse and Rawson United (Limited) held by the Chairman and the immediate members of his family (excluding the Managing Director) exceeds £6,000, the total called-up capital of the Company being over £6.0,000.

FOOTBALL.—On Saturday last the return match between teams from Messrs. Siemens' Bros. and Co. and Messrs. Johnson and Phillips was played at Charlton Park under Rugby rules, the game ending in a win for Messrs. Siemens' team by two tries (four points) to nil. The former match between these teams resulted in a draw.

TELEGRAMS: "INDICES," LONDON.

WHEATLEY KIRK, PRICE and GOULTY

(ESTABLISHED 1850).

ELECTRICAL AUCTIONEERS, VALUERS, AND ARBITRATORS.

49, QUEEN VICTORIA STREET, LONDON, E.C.

And Albert Square, MANCHESTER.

LANCASHIRE AND YORKSHIRE RAILWAY

CONTRACTS FOR STORES.

The DIRECTORS are prepared to receive TENDERS for the SUPPLY of the Company's ordinary requirements of the following Articles during the twelve months ending 30th April, 1894:—

No.
1 Baskets.
2 Brass and Copper Tubing.
3 Brushes.
4 Cloth (Oil).
5 Colours
6 Copper Rivets and Washers.
7 Cordage.
8 Creosote.
9 Emery.
10 Fire Hose.
11 Gas and Water Fittings.
12 Glass (Sundry) and Lenses.
13 Hair and Hair Seating.
14 Harness Fittings.
15 Lead.
16 Leather.
17 Mats and Matting.
18 Naphtha.
19 Oil (Engine).
20 ,, (Gas).
21 Oil (Linseed).
22 ,, (Olive).
23 ,, (Paraffin).
24 ,, (Petroleum).
25 ,, (Rape).
26 Packing, for Engines.
27 Screws.
28 Signal and Telegraph Fittings.
29 Signal and Telegraph Wires.
30 Springs (Spiral).
31 Straw.
32 Tin (Sheet) and Zinc.
33 Tubes, Copper, for Boilers.
34 ,, Steel ,,
35 Wire.
36 Wire Rope.

Way Materials.

37 Crossing Timber.
38 Sleepers.

Further particulars and Forms of Tender may be obtained on application at the Stores Department, Osborne-street, Manchester, where parties are requested to call and examine the samples before tendering. The Sample Room will be open for this purpose from the 20th to the 30th March inclusive, between 10 a.m. and 4 p.m.; Saturday, 10 a.m. to 12 noon.

Tenders, properly endorsed and addressed to the Directors, must be lodged with the Secretary not later than Ten o'clock on the morning of MONDAY, the 3rd day of April next; any received after that date will not be considered.

Separate Forms of Tender will be provided for each Contract; parties applying are therefore requested to state the particular Contract for which they propose to submit Tenders.

The Directors do not bind themselves to accept the lowest or any Tender.

C. W. BAYLEY, Secretary.

Hunt's Bank, Manchester.
17th March, 1893.

COUNTY BOROUGH OF HUDDERSFIELD.

ELECTRIC LIGHTING, MARKET HALL.

The CORPORATION of HUDDERSFIELD invite TENDERS for the ELECTRIC WIRING and FITTINGS required for LIGHTING a portion of the MARKET HALL by ELECTRICITY.

Specification, plans, and form of tender, may be obtained from Mr. A. B. Mountain, Borough Electrical Engineer, Gasworks-street, Huddersfield, to whom tenders must be sent not later than Saturday, the 1st April, 1893, endorsed "Tender for Electric Lighting of Market Hall."

H. BARBER, Town Clerk.

Town Hall, Huddersfield, 9th March. 1893.

BOROUGH OF BRIGHTON.

ELECTRICITY WORKS.

NOTICE is Hereby Given, that the COUNCIL of the said Borough will receive TENDERS from such persons as may be willing to enter into a Contract for the SUPPLY and ERECTION of ELECTRIC ARC LAMPS, SWITCHES, and LAMP CANOPIES.

Specifications can be obtained on application at my Office at the Town Hall, Brighton.

Sealed Tenders, addressed to me and endorsed "Tender for Arc Lamps," must be left at my Office before Ten o'clock in the forenoon on TUESDAY, the 4th day of April, 1893.

A fee of One Guinea will be charged for the Specification, which will be refunded on the return of the Specification accompanied by a bona fide Tender on or before the above-mentioned date.

The Council do not bind themselves to accept the lowest or any Tender.

FRANCIS J. TILLSTONE, Town Clerk.

Town Hall, Brighton, 21st March, 1893.

TO CAPITALISTS, GENERAL AND ELECTRICAL ENGINEERS, AND OTHERS,

TENDERS are invited for the STOCK, PLANT, MACHINERY and EFFECTS of a going concern in the Electrical and General Engineering trade, together with its PATENTS, LICENCES and GOODWILL, and the trade name of the same. The business has been established in the West Riding of Yorkshire for over fifteen years.

The General Engineering Shops are fitted with the most modern tools for turning out high-class work.

The Dynamo, Electric Light and Construction Departments, are similarly laid out with every modern appliance.

The Telegraph, Telephone and Railway Signalling Departments are fitted up with the most modern automatic and other machinery for producing work in large quantities at a minimum cost.

Particulars and all information and permission to view may be obtained at the offices of Messrs. LAKEMAN and OLIVER, Prudential Buildings, Park Row, Leeds.

Tenders must be sent in to Messrs. Lakeman and Oliver not later than WEDNESDAY, the 12th April, 1893.

GLOUCESTERSHIRE.

TO BE SOLD OR LET.—Extensive FREEHOLD MILLS with warehouses, manager's house, cottages, and other buildings. Good water and steam power. Situate close to railway station midway between Gloucester and Bristol. Immediate possession.—Apply, CHANTER AND CO., Solicitors, Wotton-under-Edge.

THE Telegrams: "CARWHEEL LONDON."

ELECTRIC & GENERAL CONTRACT CORPORATION, Limited.

Electric and other works for Local Authorities, Promoters, &c., undertaken and financed.

35, PARLIAMENT STREET, LONDON, S.W.

THE EASTERN EXTENSION, AUSTRALASIA AND CHINA TELEGRAPH COMPANY (Limited).

FIVE PER CENT. AUSTRALIAN GOVERNMENT SUBSIDY DEBENTURES.

NOTICE is Hereby Given that in terms of the TRUST DEED, dated 10th May, 1879, the TENTH DRAWING for payment of the above Debentures (353 IN NUMBER) will take place in the presence of a Notary Public of the City of London, on Thursday, the 6th day of April next at 11:30 o'clock, at the Offices of the Company, Winchester House, 50, Old Broad-street, in the City of London.

By order of the Board,

F. E. HESSE, Secretary.

Winchester House, 50, Old Broad-street, E.C.,
22nd March, 1893.

Nine Words to the Line.

SITUATIONS VACANT AND WANTED, &c.

WANTED, a capable ELECTRICAL ENGINEER, with fair connection, and about £2,000 capital, to join a well-established business in London. Principals only.—Apply, "A. L.," *Electrician* Office, Salisbury-court, Fleet-street, E.C.

ELECTRICAL ENGINEER (21) desires ENGAGEMENT, good theoretical training, experience in Drawing and Engineers' offices of large Contractors. Had charge of construction and maintenance at central station, and laying of mains. Good tester. Excellent references.—Address, 1207, *Electrician* Office, Salisbury-court, Fleet street, E.C.

ELECTRICAL ENGINEER, 7 years' experience, mechanical and electrical, good draughtsman, theoretical knowledge, just finishing engagement installing central station, seeks RE-ENGAGEMENT, home or abroad. Excellent testimonials.—Address 1208, *Electrician* Office, Salisbury-court, Fleet-street, E.C.

SCIENTIFIC, Electrical and Optical Instrument Lathe Hand, requires SITUATION. Good references. Long experience.—MATHEWS, care of *The Electrician* Office, Salisbury-court, Fleet-street, E.C.

YOUNG MAN wishes to LEARN the ELECTRIC LIGHT, would not mind paying a small premium.—E. RICHARDSON, Woburn, Bedfordshire.

WANTED, SITUATION as IMPROVER. Good experience in lighting and bench work.—Apply, 85, Sefton-street, Southport.

A GENTLEMAN of business habits, with opportunity of introducing considerable installation work, seeks practical PARTNER with capital.—Apply, 1211, *Electrician* Office, Salisbury-court, Fleet-street, London, E.C.

J. WEEKS AND CO., Horticultural Builders to Her Majesty, H.R.H. the Prince of Wales, H.M. Government, Admiralty Dept., War Dept., Royal Hort. Soc., Royal Botanic Soc., Parks and Public Buildings. Patentees of the Duplex Upright Tubular Boilers. King's-road, Chelsea, S.W.

Miscellaneous Advertisements, Plant Wanted and for Sale, &c., &c., continued on next page.

M. THEILER & SONS,

TELEGRAPH ENGINEERS,

86, Canonbury Road, London, N.

Makers of High-class ELECTRICAL INSTRUMENTS of every description.

FOR VENTILATING AND COOLING ENGINE AND DYNAMO ROOMS,

20 HIGHEST AWARDS, including PARIS, 1889.

BLACKMAN VENTILATING CO. (Ltd.),
63, FORE STREET, LONDON, E.C.

Hosted by Google

WANTED, and FOR SALE.

ELECTRIC LIGHTING and BELL-WORK BUSINESS FOR DISPOSAL, London, W.; excellent premises, consisting of good modern-fronted front shop and large, light, dry basement; moderate rent; to an immediate purchaser a good discount will be taken from cost price of goods or valuation; satisfactory reasons given for disposal; about £500 will complete the purchase.—Apply by letter, to Mr. H. BOURN, Baythorn End, Halstead, Essex.

J. WEEKS AND CO., King's-road, Chelsea, S.W., supply all kinds of Boilers, their improved and other Valves, tested Hot-water Pipes, Castings, Connections and Fittings at lowest retail prices.

MESSRS. DEBENHAM, TEWSON, FARMER, and BRIDGEWATER have a large selection of SHOWROOMS, OFFICES, WAREHOUSES, and FACTORIES suitable for ELECTRICAL ENGINEERS.
Their Monthly List is now ready, and may be obtained at their Offices, 80, CHEAPSIDE, E.C., or will be forwarded free by post

"THE ELECTRICIAN" ELECTRICAL TRADES' DIRECTORY AND HANDBOOK FOR 1893.
NOW READY, price 7s. 6d., post free 8s. 3d., abroad 8s. 10d.
More than 1,000 pages of RELIABLE Matter. The only COMPLETE Electrical Directory.
"THE ELECTRICIAN" PRINTING AND PUBLISHING CO., Ltd., Salisbury-court, Fleet-street, London, E.C.

THE ELECTRO-HARMONIC SOCIETY.
A SMOKING CONCERT will be held on FRIDAY, April 7th, 1893, at the ST. JAMES'S HALL RESTAURANT (Banquet Room), Regent-street, W., at Eight o'Clock.
Artistes.—Messrs. Lester, Albert James, Arthur Thompson, and Franklin Clive. Solo Violin, Mr. T. E. Gatehouse; Solo Pianist and Accompanist, Mr. Alfred E. Izard; Humorous Recitals, Mr. Fred. Frampton; Ventriloquist, Mr. Frederic Russell; Humorous Sketches, Mr. George Cronin.
Musical Directors.—Mr. T. E. Gatehouse and Mr. Alfred E. Izard.

THE ELECTRICAL and GENERAL ENGINEERING COLLEGE and SCHOOL OF SCIENCE.
PENYWERN HOUSE
2, Penywern Road, EARL'S COURT, S.W.
Principal: G. W. de TUNZELMANN, B.Sc., M.I.E.E.

The Complete Courses qualify Students for entry into Electrical and other Engineering Work.
The First Year's Course is arranged to qualify for entry into Cooper's Hill, the Central Institution, and the Royal School of Mines.
Extensive Laboratories, Dynamo Room, &c.
Students are regularly sent to the College by leading Engineers and Scientific Authorities, whose names are given in the Prospectus.

PLATINA SCRAPS, WANTED TO PURCHASE.
W. & J. JAMIESON, 10, Broad St., Golden Square, LONDON, W.

MICA
For all Purposes.
WAKE & SANDERS, 5, FOWKE'S BUILDINGS, LONDON, E.C.
Contractors to H.M. Government

AN ILLUSTRATED JOURNAL, *dealing with* ELECTRICAL MATTERS.
Electrical Plant
PUBLISHED on the 1st of EVERY MONTH
ANNUAL SUBSCRIPTION 6s. *Post Free.*
Editorial & Advertisement Offices: 52, QUEEN VICTORIA ST., LONDON, E.C.

NOW READY.
"HOUSE LIGHTING BY ELECTRICITY,"
POPULARLY EXPLAINED.
By ANGELO FAHIE, M.I.E.E.
Large 8vo. Illustrated. Paper Cover, 1s. Cloth and gilt, 2s.
LONDON: E. and F. N. SPON. DUBLIN: J. FALCONER. NEW YORK: SPON and CHAMBERLAIN.
To be had of all Booksellers.

"PATENTS: SOME POPULAR DELUSIONS.'
W. Lloyd Wise, Esq., J.P., C.C., Fellow of the Chartered Institute of Patent Agents, London. See CALVERT'S MECHANICS' ALMANAC for 1893. Price 4d.
MANCHESTER: JOHN HEYWOOD, Deansgate; and JOHN CALVERT, 99, Great Jackson-street.
LONDON: JOHN HEYWOOD, 2, Amen-corner.

NINTH EDITION of MUNRO and JAMIESON'S ELECTRICAL POCKET BOOK.
ELECTRICAL RULES & TABLES
(A POCKET BOOK OF).
For the use of Electricians and Engineers.
By JOHN MUNRO, C.E., & Prof. A. JAMIESON, F.R.S.E., M.I.C.E., M.I.E.E.
NINTH EDITION, Pocket Size, Leather, 8s. 6d.
The NINTH EDITION has again been carefully revised and enriched with fresh matter, including several important communications by leading authorities on Electro-Technics.
LONDON: CHAS. GRIFFIN & Co., Limited., Exeter Street, Strand.

Just Published, Crown 8vo, 630 pages, with 350 Illustrations. 12/6 Cloth.
THE STANDARD ELECTRICAL DICTIONARY
A Popular Dictionary of Words and Terms used in the Practice of Electrical Engineering.
Comprising upwards of 3,000 Definitions.
By T. O'CONOR SLOANE, Ph.D.
Author of "Arithmetic of Electricity," &c.
LONDON: CROSBY LOCKWOOD & SON, 7, Stationers' Hall Court, E.C.

"THE PATENTEES' HANDBOOK,"
BY
J. G. LORRAIN, M.Inst.E.E., M.Inst.M.E.,
CHARTERED PATENT AGENT,
Gives full information and advice to intending Patentees. Sent post free on application to Mr. J. G. LORRAIN, Norfolk House, Norfolk-street, Strand, London, W.C.

Messrs. WILLIAMS and NORGATE, Importers of Foreign Books, have weekly parcels from the Continent with all the new Scientific Books.
(*Foreign Prices*).
14, HENRIETTA STREET, COVENT GARDEN, LONDON, & 20, S. FREDERICK STREET, EDINBURGH.

THE LATEST ELECTRICAL NOVELTY.
ROBERTSON'S PATENT
ELECTRIC CIGAR LIGHTER.

Size 6½in. by 6½in.
Price (packed in box, post free) 21s.
Is absolutely safe. Machine complete in itself.
Generates its own Electricity.
So simple a child can work it.
Lights instantaneously on pressing knob.
3,000 lights at the cost of 6d.
Lasts a lifetime.
SHOULD BE IN EVERY SMOKING-ROOM.
These Electric Lighters are made of the best quality nickel-plate, and are of first-class workmanship.
ROBERTSON & CO.,
PATENTEES AND MAKERS,
234, SAUCHIEHALL STREET, GLASGOW.
A LIBERAL DISCOUNT TO THE TRADE.

A WEEKLY ILLUSTRATED URNAL OF

ELECTRICAL ENGINEERING, INDUSTRY AND SCIENCE.

No. 775.—Vol. XXX. FRIDAY, MARCH 24, 1893. PRICE SIXPENCE.
Annual Subscription (U. K.), 19/6

NOTES.

Challenges are not uncommon in the engineering world, but competitive tests rarely take place. At least two such challenges have been made in connection with electrical engineering, but both of them have fallen flat. Mr. Dowson has recently offered to back his gas-generating plant and a 100-H.P. gas-engine against any steam-engine, for fuel consumption on an ordinary electric-lighting load factor. He proposed to place the complete gas producer on a weighing machine, and to connect it with the engine by a hydraulic joint. Stand by losses and working consumption would be continuously recorded. Unfortunately, his challenge was too wide; it was anybody's business to take it up, and therefore nobody has done so. But, unlike other less enthusiastic inventors, Mr. Dowson has not contented himself with winning a victory "by default." He has completed arrangements for a thorough trial, probably at the end of next month, and it is only necessary to say that he has engaged the services of Prof. Kennedy, to satisfy everybody that it will indeed be thorough. A 100-H.P. (effective) Crossley engine will run two Crompton dynamos, the whole load will be absorbed by resistances, and the output will be varied to imitate, as far as possible, the actual requirements of a central station. There is every reason to expect that Mr. Dowson will beat record on this occasion, if, indeed, there is anything that has yet been arrived at by sufficiently careful measurement to be called a record.

The withdrawal of the tramway clauses in the Salford Corporation Improvement Bill shows in a very striking manner the inevitable result of the insistance by the National Telephone Company of the insertion in all tramway Bills of the obnoxious Birkenhead clause or its equivalent. If the overhead trolley and earth return are, by their very nature, unacclimatisable in this country, electrical engineers must, of course, endeavour to do without them. But until this is proved it is a grave tactical error to allow the National Telephone Company to perpetuate the anachronism of single-wire telephone circuits, and to quietly snuff out electric traction into the bargain. The National Telephone Company is, of course, quite right, from its own point of view, in securing the insertion of protective clauses wherever it can, and the electric-tractionists would do well to imitate their antagonist's aggressive action. Fortunately, in this particular instance, as at Leeds, all existing tramways can be worked by electricity without the leave of the National Telephone Company, and the only immediate result of its action, as far as Salford is concerned, is to render the *extension* of the tramway system difficult, if not impossible.

It has been courteously pointed out by a contemporary that in an editorial note appearing in our issue of March 10th, we did some injustice to the House-to-House Company by inadvertently omitting to include the item "salaries" in the total "sheer-cost" of production of the Kensington and Knightsbridge Company for 1892, thus making the latter Company's figure of merit compare more favourably than it should with that of the House-to-House Company. To make matters clear, we append the component items just as they are given in the two Companies' accounts, which we may remark are drawn up on different lines:—

Kensington and Knightsbridge Company.

	£	s.	d.
To manufacturing electricity, coal, oil, water, waste, wages, and sundries	3,746	11	4
To salaries	975	12	6
	£4,722	3	10

House-to-House Company.

	£	s.	d.
1. To coals or other fuel, including dues, carriage, unloading, storing, and all expenses of placing the same on the works	2,803	12	5
2. To oil, waste, water, and engine-room stores	791	5	1
3. To *proportion* of salaries of engineers, superintendents, and officers	620	6	2
4. To wages and gratuities at generating station	1,383	15	1
	£5,603	18	9

Our contemporary volunteers the estimate of £314 as the *proportion* of salaries chargeable to the "sheer-cost" of the Kensington and Knightsbridge Company. Adopting this, its total is then £4,060. 11s. 4d., instead of the £3,746 originally figured out, as compared with £5,603. 18s. 9d. of the House-to-House Company.

In connection with the remarkable experiment described in another column by Prof. Elihu Thomson, it is of interest to read the views of Oliver Heaviside concerning the action of conductors on magnetic fields, which are fortunately printed in the present issue. The change of the force acting on the copper disc from a repulsive to an attractive force, is no doubt in some way due to the improvement in the magnetic circuit as the copper disc is brought nearer the core of the electromagnet, but even so a fuller explanation seems needed. The importance of eddy currents in shifting the lines of force has been prominently brought out by Prof. J. J. Thomson,

Hosted by Google

who has shown that even in transformers where the iron core is well laminated, the altered distribution is of noticeable value. With large discs of low-resistance copper placed just over the core the effect must be very marked indeed, and, when looked at from this point of view, it is not surprising to find the effect described by Prof. Elihu Thomson. When the disc is at a moderate distance from the core, the distribution of the lines of force is probably not much affected, but when it is brought quite close to the core the lines are shifted so as to avoid going through the copper.

Probably experiments of this kind will remain to a great extent unexplained until some simple way is discovered for plotting the lines of force due to alternating currents. We have already suggested the use of copper filings for this purpose, but apparently this method is not sufficiently sensitive, the currents induced in the filings not being sufficiently strong to give them a set. A suspended disc of copper might be tried, or possibly a test coil connected with a delicate alternate-current voltmeter. There is little doubt that any method of plotting the lines of force generated by alternate currents would be of great value in investigating alternate-current phenomena.

Until some actual tests are published with regard to the working of non-synchronous alternate-current motors, there seems little to be gained from the consideration of their theory, especially as the most striking property of the machines is their inability to start. Mr. Kingdon's views, which we publish in another column, possess, however, some interest, since, if they are correct, the phenomenon of hysteresis, usually only a source of waste, may possibly in the future be turned to useful account.

We have already opposed the view that the rotation in a Tesla or Brown motor is due to hysteresis in the iron; and can hardly support Mr. Kingdon's attacks on what he calls the self-induction theory, though, no doubt, much useless mathematical work has been written about self-induction, and this word has often been used to cloak ignorance or vague knowledge. The term is not a good one, but the quantity it refers to is important, since it is closely connected with the magnetising or "idle" currents, the consideration of which is highly necessary in alternate-current work. The need of distinguishing these "idle" currents, which are in quadrature with the volts, from the "working," or load, currents is now generally acknowledged, although Mr. Kingdon does not appear to think so, since he refers to what he calls the usual view that "secondary currents are in quadrature with the inducing primary currents." This view may have been usual some years ago when the distinction we have alluded to was but little understood, but it is now quite exploded. Mr. Kingdon has little difficulty in disproving it, and arrives at the well-known result that in a transformer the primary and secondary currents are in opposite phase. But this conclusion, however true for transformers, the magnetic circuits of which are fixed, is not necessarily true for motors, which are really transformers, the iron circuit of which is in motion. All that Mr. Kingdon has shown is that hysteresis in the iron would produce an effect of the kind described. The magnitude of the effect caused in this way would, we believe, be excessively small.

Some interesting information on "indirect lighting," that is, illumination by diffused reflectors, will be found in another column, in an article from the German. A loss of over 50 per cent. seems a heavy price to pay for the uniformity of illumination and absence of glare, but since such a system will allow arc lamps to be used where they would not have been tolerated before, and when the 15 to 30 per cent. absorption by ground or opal globes is set against it, the system is worthy of careful consideration. We cannot approve of opal glass as an upper reflector for indirect lighting. For a lower reflector, partly reflecting and partly transmitting, it may be useful, but the upper reflector should be solid white, and probably nothing could excel good enamelled iron or copper.

An occasional contributor has sent us more than one communication on the Physics of Thought-reading, and claims that such enquiries should not be shirked. He suggests, as Prof. Houston has done, that ether vibrations may explain thought-transference. As soon as this or any other class of phenomena really comes within the domain of physical science we will try to find space for its discussion. One criterion of its inclusion should be a capability of measurement. Hertz's researches were nothing if not quantitative. When the wave-length of thought-transference can be even guessed at by the observation of stationary thought-nodes, or if, like gravitation, the action is found to be a definite function of the distance, the subject shall claim our attention. If thought be a form of radiant energy, it should obey the laws of optics. Reflection of thought is to be found in the phenomena of plagiarism, but how are we to measure the angles of incidence? Interference phenomena are abundant in the House of Commons, and if distortion or perversion of thought be a form of refraction, accompanied sometimes by chromatic effects, it is indeed too prevalent; though the refractive index, or, as it has been called, the coefficient of mendacity, may be difficult to determine. An elegant form of such refraction is known as hyperbole, but what is the focal length of a gross exaggeration, or the negative focus of a disparaging remark? Thought-reading may have its scientific aspects, but it does not at present come within those branches of physical science which are discussed in our columns.

Bridgend.—The Board of Trade has granted the Electric Lighting Provisional Order to the Local Board.

Birkdale Electric Lighting Order.—The Board of Trade have revoked the Birkdale Electric Lighting Order, 1883.

Bromley.—An inquiry has recently been held by a Local Government Inspector, as to the borrowing of £3,175 for the purchase of an electric-lighting station site at Bromley (Kent).

Cable Interruptions—

Gibraltar-Tangier	February 18th.
Para-Maranham	March 20th.

Hosted by Google

Obituary.—The death is announced of M. J. P. Hofstede, the head of the Department of Posts and Telegraphs at the Hague. The deceased represented the Netherlands at the International Telegraph Conferences held in Berlin and Paris, and was a perfect master of all detail in connection with his department. His large figure and genial manners will be long remembered by those brought into contact with him.

The Late Mr. E. T. Mercer.—The secretary of the Hastings and St. Leonards-on-Sea Electric Light Company informs us that a fund is being raised by subscription for the widow and family of the late Mr. Mercer, who met with a fatal accident on the 9th inst. whilst returning to Hastings in the London express. Contributions to the fund should be sent to Mr. F. E. Burton, the Secretary of the Hastings Company.

Royal Institution.—The following are some of the lecture arrangements after Easter :—Prof. Dewar, five lectures on "The Atmosphere"; Mr. James Swinburne, three lectures on "Some Applications of Electricity to Chemistry" (the Tyndall Lectures). The Friday evening meetings will be resumed on April 14th. Discourses will probably be given by Prof. A. B. W. Kennedy, Mr. Shelford Bidwell, Lord Kelvin, Prof. Osborne Reynolds, and Prof. T. E. Thorpe.

The Manufacture of Cored Carbons.—Messsrs. Mahla and Braun, of Nuremberg, instead of introducing the cores of their arc light carbons in a state of paste into the previously finished hollow rod, complete the core first. The core is then placed in a mandrel contained in a press, in such a manner that as the mass of carbon paste is pushed along under the action of the plunger, it carries the core, which projects slightly beyond the mandrel into the carbon paste, along with it. In this process it is only necessary to guide the core into the mandrel, and the work then goes on automatically.

The London Telephone Service.—A statement, for which we have been unable to obtain official conformation, has been going the round of the Press to the effect that the National Telephone Company proposes "almost immediately" to reduce the prices of private-house telephones in London, giving communication over the whole Metropolitan area, from £20 a year to £10 a year, subject to the condition that they are taken upon a five years' contract. The price of business telephones will remain as at present, but the National Company promises immediately to adopt the twin-wire system.

Yarmouth.—At the monthly meeting of the Town Council last week, the subject of the electric lighting of the borough, at an estimated cost of £15,000, was under discussion. Resolutions adopted at public meetings, protesting against the scheme, were submitted. The Chairman of the Electric Lighting Committee moved the adoption of the Committee's report, which recommended that the scheme for lighting the town by electricity should be carried out without loss of time. When the question was submitted to the vote it was found that the opponents to the scheme were in a decided minority.

Municipal Electric Lighting at Hackney.—At the last meeting of the Hackney Vestry a discussion arose upon a report of the Parliamentary Committee upon the subject of the Pitfield-street Iron Works site, now in the market, which the Committee recommended as most suitable for the combined purposes of electric-lighting station, and baths and washhouses. They suggested that the Vestry should offer the owners the sum of £33,000 for the whole of the site, which consisted of about 1½ acres of houses, shops, and vacant land, subject to a good title being adduced, and to each party paying their own law costs. An amendment that the Vestry should offer £28,000 was carried.

Forthcoming Books.—Messrs. Whittaker and Co. will issue in their Specialists' Series a work on "The Dynamo," by C. C. Hawkins and F. Wallis, and a new edition of Sir David Salomons' work on "The Management of Accumulators." They have also in preparation in the Library of Popular Science an introductory work on "Electricity and Magnetism," by S. Bottone. Mr. Perren Maycock has completed the second part of his work on "Electric Lighting and Power Distribution," and it will be issued in a few days. Messrs. Griffin and Co. announce "Griffin's Electrical Price-Book," edited by Mr. H. J. Dowsing, and the tenth annual issue of the "Year-Book of Learned and Scientific Societies."

Albert Medal.—The Council of the Society of Arts will proceed to consider the award of the Albert Medal for 1893 early in May next, and they therefore invite members of the Society to forward to the Secretary, on or before April 15th, the name of such men of high distinction as they may think worthy of this honour. The medal was struck to reward "distinguished merit for promoting arts, manufactures, or commerce," and has been awarded in previous years to Michael Faraday (1866), Sir W. Fothergill Cooke and Sir Charles Wheatstone (1867), Sir William Siemens (1874), Sir George B. Airy (1876), Sir William Thomson (1879), James Prescott Joule (1880), Prof. Helmholtz (1888), Thomas Alva Edison (1892).

The Electric Light at the Mansion House.—At the meeting of the Common Council last week the General Purposes Committee asked for authority to pay the accounts of the City of London Electric Light Company for current supplied to the Mansion House for the quarter to Christmas last (£306 11s. 4d.). Mr. Salmon said the total cost of lighting the Mansion House by electricity was about £700 per annum—about double that of gas. The Committee had made no arrangement with the Company in question, and it was not improbable that at some future time they would generate their own electricity. The Court, having approved of the payment of these accounts, agreed also to a report from the same Committee, recommending that the two large windows in the Egyptian Hall should be lighted by gas instead of electricity.

The Electric Traction Question at Coventry.—Last week there was a lengthy and heated discussion at the Town Council meeting over the tramways question. The Council has already consented to Mr. Graff Baker, the owner, equipping the line electrically, but owing to the conditions imposed by the General Works Committee there was some danger of the negotiations falling through and Mr. Baker resorting to steam. When the correspondence was laid before the Council, it was proposed that the matter should be at once dealt with by the larger body, and taken out of the Committee's hands. As Mr. Baker had conceded some of the Committee's points, a compromise was finally come to, some fresh letters which had been received being referred to the Committee, on the understanding that no time was lost in completing the agreement between the Council and Mr. Baker.

Electrical Communication with Lighthouses.—In the House of Commons on Tuesday, the President of the Board of Trade was asked whether, inasmuch as the recommendations unanimously endorsed by the Commissioners as a means of saving life at sea involved a very small estimated cost, the Government intended without any further delay to carry out the recommendations of the Royal Commission upon Electrical Communication with Lighthouses and Lightships made in December last. Mr. Mundella stated in reply that a Committee had been appointed to consider and report on the best means of carrying out the recommendations of the Royal Commission. He was advised that they had now the whole matter under consideration, and would report soon after Easter. He could assure the right hon. gentleman that no unnecessary delay would take place.

Edinburgh.—The Edinburgh Town Council have now had the subject of electric lighting more or less under discussion for over three years. A few months back a Committee made the customary provincial tour of inspection, and after much labour issued a voluminous report, which required the professional assistance of Prof. A. B. W. Kennedy to elucidate it. Prof. Kennedy supplemented the Committee's vague generalities by a few particulars regarding probable first cost, annual cost, and annual income of a 40,000-light system supplying the northern half of Edinburgh. A meeting of the Lord Provost's Committee was held last week for the purpose of considering this report of Prof. Kennedy. The Committee discussed the question for two hours. The point which gave rise to the greatest difference of opinion was with regard to who was to have the working of the scheme. Some of the members of the Committee were strongly averse to the Corporation having any-

Hosted by Google

thing to do with it. The meeting finally broke up without coming to any resolution.

The Earth's Magnetism.—In the course of a lecture, entitled "The Ether and its Functions, or Demon Worship in Science," delivered last week in the theatre of the Royal Dublin Society, Prof. Thomas Preston remarked that an interesting point arose concerning the magnetism of the earth. Why should the earth be magnetised on the whole in the direction of its axis rather than in some other direction, and why magnetised at all? The ether theory seemed to point to the magnetic polarity of the earth as a natural consequence rather than as a surprising fact. For if they went back to the time when the earth was a fluid mass rotating about its axis, they should expect to find that on account of that rotation the atoms would set their axis parallel to the axis of rotation, that was, with their faces towards the poles, and they would have an arrangement which would give the earth the magnetic properties it actually possessed; and that arrangement they should also expect to be ever and anon disturbed and partially destroyed by the internal movements and crust motions, and such mass motions might account for the changes and disturbances which were still in operation in the earth's magnetism.

The City Lighting.—At Wednesday's meeting of the Commissioners of Sewers, the Finance and Improvement Committee brought up a report relative to an application of the City of London Electric Lighting Company for the Commission's assent to their introduction of a Bill for amending Section 8 of the Electric Lighting Order. The object of the proposed Bill would be to abrogate the provisions for setting aside 7½ per cent. on the capital expended, for depreciation. The Committee were unable to recommend compliance with the application. Mr. W. H. Pannell said he thought the report should be reconsidered, and his suggestion was accepted by the Committee.——The *City Press* of Wednesday delivers itself of the following :—

"The conduct of the City Electric Lighting Company deserves to be looked into. Not only is the Company putting its work forward at its leisure, so that it will probably be opening our streets for the next twelve-months, not only is it laying down extra tubes so as to transmit power as well as light, but the light sent is intermittent and unreliable, and the price charged is much greater than other companies are asking. The Lord Mayor told the Court on Thursday that the light at the Mansion House sometimes went out, and while the City Company is charging 7d. per unit, I find that the Westminster Company is only charging 5d. for a strong, bright, unflickering light. Unfortunately the City contract gives a maximum of 8d., so that I fear there will be a great many misunderstandings before things are reduced to working order."

Efficiency of Schuckert Dynamos with a Small Load.—The official certificates of the dynamos from 350 to 500 H.P., supplied by Schuckert and Co. to the Municipal Central Stations of Düsseldorf and Hanover, give the following results.

Düsseldorf Central Station.

Output in kilowatts.	Efficiency of steam engine.	Efficiency of dynamo.	Total commercial efficiency.	Watts per I.H.P.*
20·75	86·00 per cent.	91·6 per cent.	78·8 per cent.	588
24·60	85·26 ,,	92·4 ,,	78·8 ,,	588
26·99	87·30 ,,	92·4 ,,	80·7 ,,	602
36·16	87·94 ,,	92·7 ,,	81·52 ,,	608

* English horse-power of 746 watts.

At Hanover the efficiency of dynamo and steam engine are not given separately, but the total efficiency, instead of being 76·5 per cent., has been proved to be 81·8 per cent., which, after comparison with the above-mentioned figures, is equivalent to an efficiency of 88 per cent. for the steam engine and 93 per cent. for the dynamo. For a smaller load, viz, two-thirds the maximum output, the efficiency is only 1 per cent. less. As the machines work in combination with secondary batteries, they need never be worked with a smaller load than two-thirds the maximum, so that high efficiency is practically attained with the average output of the central station. These figures have been obtained from tests made by Prof. Kittler, of Düsseldorf, and Prof. Kohlrausch, of Hanover.

The Green and Field Electric Traction Patents.—As the Green electric traction patents have recently been purchased by the General Electric Company of America, it may be presumed that they are supposed to be of some legal value, and their chief claims may not, therefore, be without interest. Green's first patent (No. 465,407) was applied for on September 15, 1879, and was granted December 15th, 1891. Its third claim runs as follows :—"The combination, substantially as set forth, of a railway track, one or more stationary means of electric supply, electrical conductors extending from said means of electric supply along the lines of said track, and consisting wholly or in part of the rails thereof, vehicles movable along said track, electrodynamic motors fixed upon said vehicles for imparting motion thereto, and wheels supporting said vehicles upon the track, and also serving to maintain continuous electrical connection between said means of electric supply and said motors, substantially as described." Green's second patent (No. 465,432) was applied for on May 15, 1886, and granted on the same date as the first. Its first claim is as follows :—"The combination of one or more stationary sources of electric current, conducting circuit formed wholly or in part of an insulated line of rails of a railway track, a wheeled vehicle movable upon or along said line of rails, one or more rotating electric dynamic motors mounted upon said vehicle for propelling the same and included in said circuit of conductors, and a circuit-controller placed on said vehicle and also included in said line of conductors, substantially as described." Another so-called master patent is that of Mr. Stephen D. Field (No. 407,188) applied for March 10, 1880, and granted July 16, 1889. The first claim reads as follows :—"The combination, substantially as herein before set forth, of a stationary dynamo-electric generator driven by a suitable motor, a circuit of conductors composed in part of an insulated or detached section of the line of rails of a railway track, a wheeled vehicle movable upon or along said insulated section of track, an electro-magnetic motor mounted upon said vehicle for propelling the same, and included in said circuit of conductors, and a circuit-controlling device placed upon said vehicle."

Cardiff.—A local Government Board inquiry was held at Cardiff on Wednesday last week into an application made by the Town Council for sanction to borrow £32,500 for purposes of electric lighting. The borough engineer said that for some years previously to 1890, the Brush Company had supplied electric light to a large number of customers, but in that year many of their overhead wires had become decayed, and the Board of Trade insisted upon the wires being placed underground. As a result the Company closed their station in October, 1890. The present application was to enable the Corporation to carry on the electric lighting. The site adopted was at a distance of about one mile from the area of supply, but it had the great advantage of being alongside the Great Western Railway, and at a depth of seven or eight feet below the surface an abundant supply of water could be obtained for condensing purposes. Mr. W. H. Massey said that although he had for many years, and of his own choice, not acted for local authorities in other districts, he readily undertook the duties of consulting electrical engineer in this case, believing that Cardiff was one of the few places in the kingdom where electric lighting might be carried on at a profit, and where the whole of the work connected with the establishment and maintenance of the necessary works could be placed under the control of the borough engineer and his staff, thus avoiding the complications which had arisen in other towns, where an electrical engineer had been specially appointed to take permanent charge of such works. He produced an approximate estimate of expenditure. Mr. Sydney F. Walker desired to point out to the Inspector the fact that there were coming into Cardiff four million gallons of water per diem, and they came in at a considerable pressure, and he asked what objection there was to water power being used. The borough engineer said that with a life-long experience of waterworks he knew they could not possibly rely upon the regularity of the supply. After further discussion, Mr. Walker expressed himself as satisfied. He then went on to say that part of the Corporation scheme was to light the streets with arc lamps. He desired to call attention to the rapid headway made by the large incandescent lamp. The inquiry then closed.

ERNST WERNER VON SIEMENS.

Dr. Ernst Werner von Siemens was borne at Lenthe, in the Electorate of Hanover, in 1816. He was the eldest of seven brothers, all of whom have attained distinction in the pursuit of science, while William—the best known of the family in this country—Carl, and Frederick displayed a genius almost equal to that of Werner. The parents of this family of scientists were Christian Ferdinand Siemens, a man possessed of considerable means and engaged in the occupations of farming and forestry, and Eleonore Deichmann. In the virtue of perseverance particularly, Werner has testified to the benefits of his father's example and encouragement.

Werner's early life was spent, first in acquiring an excellent education at the Gymnasium of Lubeck, and afterwards in the study of military practice and theory. At the age of 28 he was appointed Superintendent of Artillery Workshops' and devoted his attention to the applications of mechanical, electrical and chemical science to the defences of his country. Among his more practical military researches may be mentioned the application of electricity to the firing of submarine explosive mines, and the accurate measurement of the velocity of projectiles. The first of these became useful at Kiel, at which place Siemens was stationed when that military port was attacked by the Danish fleet, in 1848. The apparatus for the second of these inventions consisted of a polished steel cylinder, set rotating at a high and uniform speed, which was finely marked by the spark from a Leyden jar when the moving projectile completed the discharging circuit. The inventor claimed for this machine a sensitiveness sufficient to enable 1-10,000th of a second of time, or 1-100th of a foot of motion to be recorded. About this time, Werner Siemens proposed the use of subterranean instead of overhead telegraph lines, and invented a machine for serving the conductor with seamless guttapercha.

The history of gutta-percha is, indeed, a most striking instance of the way in which we moderns are rapidly and wastefully exhausting the bountiful supplies of Nature. Introduced into Europe for the first time as an article of commerce exactly half a century ago, the electrical industry is already threatened not merely with a famine but with the complete exhaustion of the supply of gutta-percha. In a modestly and clearly written little pamphlet, published in 1851, Werner Siemens gave a graphic and interesting account of the many difficulties encountered by himself and his colleagues of the Commission zur Vorbereitung der Telegraphenanlagen in Preussen, when in the spring of 1848 they sought to make use of gutta-percha as an insulator for the underground wires which were hastily ordered to be laid between Berlin and Frankfort-on-the-Main and Aix-la-Chapelle in view of the then menacing civil disturbances. Vulcanisation was attempted, but the excess of sulphur, the overheating and the absence of anything in the nature of a "separator" between the copper conductors and the over sulphured gutta-percha, together with the crude character of the machinery employed, resulted in troubles of all kinds. The adulteration of gutta-percha which has now attained the proportions of a fine art was, it is worth noting, even in 1848 a source of annoyance and the cause of many a breakdown.

Shortly after this Werner Siemens retired from the army, and commenced to devote his whole energies to investigations in theoretical and applied science. To describe all the inventions and discoveries which resulted from this work, would require a large volume; we must here be content with briefly enumerating only the more important of them. When quite a young student, Werner had succeeded in electro-gilding a surface of metal, and, better than this, had succeeded in selling his patent for a sum of money which enabled him to further prosecute his research into electro-chemistry. In the year following his retirement from the army he published a note on the electrolytic separation of nickel and cobalt. His other achievements in practical electricity include dial and printing telegraphs, the duplex telegraph circuit, apparatus for localising faults in electric cables, and the "Siemens' unit" or standard of electrical resistance, which has now given place to the *ohm*. Later than these came the polarised relay, an electrical range-finder, and the crowning inventions of the self-exciting dynamo and of the method of armature winding known by his name. Mining operations have been aided by the practical magnetic ore separator and the electric hammer which he invented, the latter being the precursor of the electric rock-drill. The first electric railway ever constructed was put up by Messrs. Siemens and Halske, of Berlin, at the Trades Exhibition in that city in 1879; and one of the earliest forms of self-regulating arc lamps is to be attributed to this prolific inventor. Among the numerous non-electrical inventions, we may notice the pneumatic dispatch—a method of transmitting small parcels—which is largely employed on the continent and in the Post Office in this country, a pneumatically-controlled torpedo, which was inspired by the outbreak of the Franco-Prussian war in 1870, and an alcoholometer which indicates the percentage of absolute alcohol in any spirit passed through it.

For his researches in pure science Werner Siemens received from the University of Berlin, in 1860, the degree of Doctor of Philosophy, *honoris causâ*, while a patent of nobility was conferred upon him by the late Emperor Frederick III. Besides these distinctions, Dr. Siemens could claim the highest scientific order of his country, that of the Prussian order "Pour le Mérite," and the honorary membership of several engineering societies. His scientific research, however, was directed towards the solution of definite practical problems rather than towards the advancement of pure or abstract science. It comprised investigations on the electrical resistance of alloys, on the heating of a dielectric during electrical discharge, on the effects of light and electricity on selenium, and on the "Electrostatic Induction and Retardation in the Cores of Cables"—this last being the title of an important paper read by him in 1857.

The scientist who knew how to explore nature, the inventor who understood how to apply to practical ends the fruits of his explorations, and the shrewd man of business who saw in the theories of science and in the inventions which he had made a means to reap a harvest for himself and his firm, was also the philanthropist and the man of heart, who knew how to scatter among the less favoured the good things he had so well earned for himself. In 1886, Dr. Siemens presented 500,000 marks to the German nation for the foundation of a national scientific and technical institution; and thus conferred a lasting boon on the civilised world. In earlier years, when the introduction of the telegraph by Siemens and Halske bid fair to ruin the business of those who had worked under the older postal system, a young lady came to Werner Siemens and told him, with tears in her eyes, that he was about to utterly ruin the business of her husband, a pigeon-post man. Dr. Siemens strongly advised the young couple to roast their pigeons, and promised his assistance if they went to London and started a news agency. The husband of that young lady was Herr Reuter, who subsequently became a baron and a very rich man. It is said that for years it was the first daily duty of Dr. Siemens to read the large number of requests for assistance which came to him from every quarter. These he would mark with the amount of money to be sent in each case; and it was very rarely indeed that his assistance was refused.

On December 6, 1892, and within one week of his 76th birthday, Dr. Siemens' life of usefulness and activity ended. He had been twice married, and left three sons and three daughters. The former of these will continue the business of the world-famed firm, from which Herr Halske, who died in March, 1890, retired in 1867, but in which Dr. Werner von Siemens took an active interest up till the few days before his death when the influenza attacked him. Not in sand, but ineffaceably in granite, has Werner von Siemens left footprints which will be seen and utilised by the generations to come.

ELECTROMAGNETIC THEORY.—XLVI.

BY OLIVER HEAVISIDE

(*Continued from page 536.*)

§ **191.** The theory of the effect of a finite degree of conductivity in the medium on electromagnetic waves is far more difficult and complicated than that of the effect of infinite conductivity. Nevertheless, we may gain a general idea of the nature of the effect by means of the substitution of simple problems for the real ones that present themselves, and also in this way obtain a knowledge of very important properties concerned. There are two ways in which we may regard the question of conductivity. First, starting from the theory of perfect conductors surrounded by perfect dielectric non conductors, we may examine the effect of introducing a slight amount of resistivity, to be then increased more and more until at last we come to conductors of high resistivity, or infinite, when we have dielectrics merely. The other way is to start with electromagnetic waves in a perfect dielectric, and examine the effect produced upon them of introducing first a small amount of conductivity, then more and more, until we come to perfect conductors again. Both ways are instructive—none the less because they give very different views of the same matter.

In the first place, it may be readily conceived that if a conductor have only a slight amount of resistivity it may behave approximately the same as if it had none, and may obstruct waves nearly perfectly internally, and likewise reflect and conduct them superficially nearly perfectly. This is true, but the element of time has to be taken into account, as it becomes of great importance when there is some resistivity, however little, instead of quite none. Suppose, for example, we have an initially steady magnetic field, and bring a conductor into it very quickly from a distance, and keep it there. If this be done quickly enough, the first effect is nearly the same as if the conductor were perfect. That is, the induction of the field will be driven out of the space it previously occupied, which is now occupied by the conductor, and pass round it tangentially, as if the conductor were of zero inductivity. It will, therefore, be mechanically acted upon by the stress in the field in a manner resembling the action upon a perfect diamagnetic body—that is, there will be a force tending to drive it from stronger to weaker parts of the field. In another form, we may say that there is a resisting force to be overcome to bring the conductor into the field and to hold it there. But this state of things will not continue. The magnetic force, which is at first only skin deep, will penetrate into the interior in time, according to a law resembling that of the diffusion of heat. Given time enough, it will assume the same distribution as if there were no conductivity, although our assumption is that there is nearly no resistivity—that is, in the ultimate state tended to, it is merely the inductivity that settles how the magnetic induction will distribute itself. Initially, there is a skin current, its total being measured by the difference in the magnetic force just outside and a little way inside the conductor, in the bulk of which there is practically no magnetic force or electric current. As in the case of a perfect conductor, Ohm's law is fully obeyed. There is no internal current, because there is no internal electric or magnetic force. They simply have not had time to get in, on account of the obstructive action of the high conductivity. It is as useless and misleading to say that one electric force is cancelled by another, as it is to ascribe the absence of magnetic force to the counteracting magnetic force of the skin current. As the magnetic force spreads into the conductor, so does the electric current, which is the curl of the former. In the end, when the magnetic force has got steady, the current ceases. There may now still be moving force on the conductor, but not of the same kind as before, it being simply the ordinary paramagnetic attraction or diamagnetic repulsion according as the value of the inductivity of the body exceeds or is less than that of the external medium.

It will be very much the same thing if we start with the conductor at rest in a neutral state in a neutral field, and then establish a steady magnetic field by some external cause. There will still be the same internal obstruction offered by the conductor, and consequent delay in the assumption of the steady state throughout it. In both cases, too, there is a necessary waste of energy involved in the process, according to Joule's law of the generation of heat by the existence of electric current in conducting matter. Thus two things happen when the degree of conductivity is not infinite. First, the reflection is imperfect at the boundary of the conductor, a portion of an incident disturbance being transmitted into it. Next, in the act of transmission and the attenuation involved, there is a loss of energy from the electromagnetic field. We shall see later more precisely the nature of the attenuating process. At present we may note that if the external field be not steady or do not tend to a steady state, so that the conductor is exposed to fluctuating forces, then the internal part of the conductor need never acquire any sensible magnetic force. Thus, if the external field be the sum of a balanced alternating, and of a field which would be steady in the absence of the conductor, only the latter part will penetrate fully into it. The former alternating part will penetrate imperfectly, the more so the greater the conductivity, and, as before said, not at all when the conductivity is perfect. With rapid alternations the region of sensible penetration is only skin-deep, consisting of layers of opposite kinds (as regards direction of the magnetic force, which is nearly tangential), with, however, so very rapid an attenuation of intensity in going inward that practically only one wave need be considered (except for short waves, like light). Of course, the heat generation is now confined to the skin. What goes in further does so by ordinary heat diffusion.

The time-constant of retardation of a conductor varies as the conductivity, as the inductivity, and as the square of the linear dimensions. This refers to the intervals of time required to establish a definite proportion of the steady state under the action of steady forces—in bodies of different size, conductivity, and inductivity, but geometrically similar. Here the two properties, conductivity and inductivity, act conjointly, so that, for example, iron is far more obstructive than copper, although its conductivity is much inferior. It is different with the heat-generation. There the inductivity and conductivity act in opposite senses, for, with the same electric force, the waste varies as the conductivity, or, with the same current-density, as the resistivity. It results that in cases of skin-conduction of rapidly alternating currents, the resistance per unit area of surface varies directly as the square root of the product of the resistivity (not conductivity), inductivity, and frequency. Thus, whilst we may increase the resistance by increasing the frequency, with a given material, and also by increasing the inductivity, we decrease it by increasing the conductivity, in spite of the fact that the internal obstruction varies as the conductivity and inductivity conjointly. The point to be attended to here is that mere internal obstruction is no necessary bar to effective skin conduction, although, of course, in a given case the resistance is greater than if the conduction were more widespread. It depends upon how it is brought about, whether by conductivity or inductivity. This is how it comes about that with the complete internal obstruction of a perfect conductor, with the effective skin reduced to nothing, there is still no resistance, and the slip of electromagnetic waves along them is perfect. But it is different when we obtain the internal obstruction by increasing the inductivity, preserving the conductivity constant. Perfect internal obstruction then means infinite resistance, and no proper slipping of waves at all. If the obstruction be not complete, it will be accompanied by very rapid attenuation of waves running along the surface when the obstruction arises from high inductivity, and by relatively very slight attenuation when it arises from high conductivity.

The repulsive force which was referred to in the case of a perfect conductor brought into a magnetic field, or when a magnetic field is created outside the perfect conductor, arises from its obstructive action, combined with the fact that it is only the lateral pressure of the magnetic stress that acts on the conductor, owing to the tangentiality of the magnetic force. This repulsive force is naturally also operative, though in a less marked form, when the conductivity is not perfect. In fact, it is operative to some extent whenever there is a sufficiently rapid alternation of the field to cause a sensible departure from full

Hosted by Google

penetration of the magnetic force, and is, therefore, strongly operative with ordinary metallic conductors with quite moderate frequency of vibration. The remarkable experiments of Prof. Elihu Thomson on this "electromagnetic repulsion" will be remembered. The phenomenon has nothing specially to do with electromagnetic waves. It is magnetic repulsion, rather than electromagnetic, using the word "magnetic" in its general sense, apart from the special fact of magnetisation when the inductivity of the conductor is not the same as that of the ether.

When a conductor is brought into an electric instead of a magnetic field, the case is somewhat different. There is in any case merely skin conduction, for there is an actual destruction of the flux displacement by conductivity. The final result therefore, is that the ultimate permanent state in the conductor is a state of perfect neutrality, just as if the conductivity were perfect. Electric conductivity destroys displacement, but it cannot destroy induction. Similarly, magnetic conductivity would destroy induction, but would be unable to destroy displacement. Thus, a magnetic conductor brought into an electric field would, in time, permit its full penetration, but if brought into a magnetic field the final result would be a state of internal neutrality, however low the conductivity. If, however, it be very low, then, whether it be of the electric or the magnetic kind, there will be an initial nearly complete penetration (owing to the removal of the obstruction), followed by subsidence to zero of the flux appropriate to the conductivity, electric or magnetic respectively. The persistence of magnetic induction, in spite of the presence of electric conductivity, is a very important and significant fact, of which I shall give a simple proof in a later Section, in amplification of my proof of 1887-8. The present method of passing from perfect to finite conductivity is unsuitable for the purpose, because in good conductors the dielectric permittivity is altogether swamped, and is therefore ignored; whilst, on the other hand, in very bad conductors the permittivity is a factor of the greatest importance. Now we can pass continuously from a non-conducting dielectric to a conducting one, up to perfect conduction, but we cannot pass the other way without having the permittivity in view all the time, which makes the matter difficult.

§ 192. As people's memories are very short, and there is some discussion on the subject, I may repeat here that the so-frequently-used word inductivity is not intended for use as a mere synonym for permeability. The latter is the ratio of the inductivity of a medium to that of ether, and is therefore a mere numeric. On the other hand, inductivity has a wider meaning, namely, such that $\frac{1}{2}\mu H^2$ is the density of the magnetic energy, irrespective of dimensions. We can only make it a numeric by assumption. Even then, it has only a fictitious identity with permeability—a forced numerical identity. Similar remarks apply to some other quantities, but they are particularly necessary in the case of inductivity, on account of the obscure and misleading manner in which the connections between induction, magnetic force, and magnetisation were formerly commonly presented (and still are sometimes), together with the misleading connection between the susceptibility and the permeability. We should write

$$p = 1 + \kappa,$$

if p is the permeability and κ the susceptibility, instead of

$$p_i = 1 + 4\pi\kappa_i,$$

where the suffix letter refers to the common irrational reckoning. The 4π is, as usual, simply nonsense, unworthy of scientific men near the end of the nineteenth century. Now introduce Maxwell's ether theory, and make $p = \mu/\mu_0$, where μ_0 is the inductivity of ether, and μ that of some other substance (with the usual reservations), then

$$\mu = \mu_0(1 + \kappa)$$

takes the place of the common

$$\mu_i = 1 + 4\pi\kappa_i,$$

which is misleading in two respects, first as regards the obstreperous 4π, and next in making μ and κ be quantities of the same kind. But κ is always and essentially a numeric, whilst μ is not. We see that the use of inductivity rather than permeability is necessary in electromagnetic theory, as a matter of logical common sense as well as for the purpose of scientific clearness. But this need not interfere with the use of permeability in its above-described sense of a ratio. If, on the other hand, one of the two words should be abolished, there can, I think, be little doubt as to which should go.

In the case of purely elastic magnetisation (without intrinsic), we have

$$\mathbf{B} = \mu\mathbf{F} = \mu_0(1 + \kappa)\,\mathbf{F},$$

where $\mathbf{B}$ is the induction and $\mathbf{F}$ the magnetic force. Here $\mu_0\mathbf{F}$ is what the induction would be in ether, so that the additional part $\mu_0\kappa\mathbf{F}$ expresses the effect of the matter present, which becomes magnetised. The ratio κ, therefore, naturally expresses the susceptibility for magnetisation of the matter. Perhaps, in passing, it might be thought that $\mu_0\kappa$ should express the susceptibility. But this will not do, because magnetisation and induction are similar. The induced magnetisation is $\mu_0\kappa\mathbf{F}$. In strictness it should not be called the intensity of magnetisation, but rather the density, if we properly carry out Maxwell's principles about forces and fluxes, or intensities and densities. $\mathbf{B}$ is a flux, therefore so is $\mu_0\kappa\mathbf{F}$, to be measured per unit area. Now, the common form is

$$\mathbf{B}_i = \mu\mathbf{F}_i = (1 + 4\pi\kappa_i)\mathbf{F}_i,$$

or

$$\mathbf{B}_i = \mathbf{F}_i + 4\pi\mathbf{I}_i,$$

if $\mathbf{I}_i = \kappa_i\mathbf{F}_i$. Here we have, apart from the 4π absurdity, an irrationality of a different kind, viz., that induction and magnetisation are made identical in kind with magnetic force, since we have the difference of two flux densities expressed by an "intensity," which is referred to unit length. Now, this may matter very little in practical calculations, but it is more than mischievous in theory. Suppose, for example, we are working with a kind of mathematics that takes explicitly into account the two ways of measuring vector magnitudes, with reference to length and to area respectively, according as they are regarded as "flux" densities or "force" intensities. Then, if we do not recognise and take account of the radical difference between $\mathbf{B}_i$ and $\mathbf{F}_i$ in the last equation, we may expect to be led to singular and unaccountable anomalies. This is, I think, what has happened in Mr. MacAulay's recent paper on the theory of electromagnetism. The remedy is easy. There should be no special limitations imposed upon the quantities concerned such as occur when permeability and inductivity are made the same.

It is also highly desirable, for the same purpose of obtaining scientific clearness and freedom from distressing anomalies, that the distinction between "induced" and intrinsic magnetisation should be clearly recognised and admitted in the formula. In the above there has been no intrinsic magnetisation. Let this now be $\mathbf{I}_0$. An equivalent form is $\mu\mathbf{h}_0$, where $\mathbf{h}_0$ is the corresponding intrinsic magnetic force. This $\mathbf{I}_0$ is of the same nature as $\mathbf{B}$. The complete induction becomes

$$\mathbf{B} = \mu(\mathbf{F} + \mathbf{h}) = \mu\mathbf{H},$$

where $\mathbf{H}$ is the complete force of the flux $\mathbf{B}$. This is the best way of exhibiting the induction. If $\mathbf{H}$ be split at all, let it be into the part involving the intrinsic force $\mathbf{h}$ and the rest. Or,

$$\mathbf{B} = \mathbf{I}_0 + \mu\mathbf{F}.$$

The other separation, namely, of $\mu\mathbf{F}$ into the ether induction $\mu_0\mathbf{F}$ and the additional part due to matter, is less useful. If done, then

$$\mathbf{B} = \mathbf{I}_0 + \mathbf{I} + \mu_0\mathbf{F}.$$

If we now amalgamate $\mathbf{I}_0$ and $\mathbf{I}$, to make, say, $\mathbf{I}_1$, the total magnetisation, intrinsic and induced, we have

$$\mathbf{B} = \mathbf{I}_1 + \mu_0\mathbf{F},$$

which, translated into irrational units, makes

$$\mathbf{B}_i = 4\pi\mathbf{I}_{1i} + \mu_0\mathbf{F}_i;$$

and lastly, omitting the μ_0 by assuming it to be unity, we obtain the common

$$\mathbf{B}_i = \mathbf{F}_i + 4\pi\mathbf{I}_{1i},$$

containing three faults, the arbitrary 4π, the equalising of an intensity and a flux, and the unnatural union of physically distinct magnetisations.

Hosted by Google

"Different men have different opinions—some like apples, some like inions." But can anyone possibly really like the roundabout and misleading way of presenting the magnetic flux relations which I have above criticised? There is no excuse for it, except that it was employed by great men when they were engaged in *making* magnetic theory, before they had assimilated its consequences thoroughly. When the rough work of construction is over, then it is desirable to go over it again, and put it in a better and more practical form. We should copy the virtues of great men, if we can, but not their faults.

Men who are engaged in practical work can hardly be expected to fully appreciate the importance of these things, because their applications are of so highly specialised a nature, in the details of which they may become wholly absorbed. They may even go so far as to say that the paper theory of magnetic induction is not of the least moment, because they are concerned with iron, and although there may be a certain small range of application of the theory even in iron, yet they are scarcely concerned with it, and, therefore, it is of no consequence. There could not be a greater mistake. A complete theory of magnetic induction, including hysteresis, must necessarily be so constructed as to harmonise with the limited theory that has already been elaborated, which is understandable when exhibited in a purified form, freed from 4π's and other anomalies. First of all, we have the ether, in which $\mathbf{B}=\mu_0\mathbf{F}$ or $\mathbf{B}=\mu_0\mathbf{H}$, because of the absence of intrinsic magnetisation. Next we come to elastically magnetised bodies in which the relation between flux and force is linear. Then $\mathbf{B}=\mu\mathbf{H}$, where μ differs from μ_0, being either greater or smaller, and is either a constant scalar, or else (with eolotropy) a linear operator. If there is no intrinsic magnetisation, $\mathbf{F}$ and $\mathbf{H}$ are still the same, and the curl of either is the current density. But should there be intrinsic magnetisation, then $\mathbf{H}=\mathbf{h}_0+\mathbf{F}$, whilst $\mathbf{B}=\mu\mathbf{H}$ still, and it is the curl of $\mathbf{F}$ that is the current density. Or, $\mathbf{B}=\mathbf{I}_0+\mu\mathbf{F}$. The next step is to make $\mu\mathbf{F}$ be not a linear, but some other function of $\mathbf{F}$, to be experimentally determined, if it be possible to express $\mathbf{B}-\mathbf{I}_0$, which is the free induction, as a function of $\mathbf{F}$. Of course, it can be done approximately. Then comes the difficult question of hysteresis. This involves the variation of $\mathbf{I}_0$ with $\mathbf{F}$, with consequent waste of energy. If this little matter be satisfactorily determined, we may expect to have a sound mathematical theory of magnetic induction in an extended form which shall properly harmonise with the rational form of the elementary theory. The divergence of $\mathbf{B}$ is zero all through. The experimental justification of this generalisation is the fact that no unipolar magnets have yet been discovered.

(*To be continued.*)

A NOVEL ELECTROSCOPE.

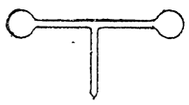
BY E. C. RIMINGTON.

In a Paper entitled "Experiments in Electric and Magnetic Fields," read by the writer in conjunction with Mr. Wythe Smith before the Physical Society last November (reproduced in this paper December 9th, 1892), an experiment was given of the illumination of an electrodeless vacuum tube rotated in a constant electric field between two charged plates.

The writer has since found that this experiment can be much more simply shown by bringing a rubbed ebonite or glass rod near to the rotating tube, when the set of double fan-shaped images of the tube will be developed nearly as brilliantly as when charged plates are employed.

The fan, however, will not be quite as symmetrical as in the case of the plates, on account of the electric field being much less uniform, since the lines of induction, will, many of them, pass to the spindle of the motor or apparatus used to rotate the tube, unless, of course, the tube be fastened to the end of a long rod of some insulating substance. When the rod is moved away from the tube, the number of images in the fan diminishes, as the electric field in which the tube is rotating is weakened.

An ebonite rod excited by being drawn once through a piece of dry flannel, will produce one image when held at a distance of over one foot from the tube, thus forming an exceedingly novel kind of electroscope. The best form of tube to employ is that given in the figure; the straight portion between the bulbs is about the bore of a spirit thermometer, the length about 5in., the T-piece is where it was connected to the pump,



and serves as a means of connecting the tube to the motor. It is not, however, even necessary to employ a motor, as twiddling the tube between the finger and thumb by the T-piece when holding it near the excited rod enables the effect to be obtained, though, needless to say, it is not so good as when the tube is rotated at a uniform speed.

This experiment is an interesting one from the fact that the extra power (infinitesimally small) required to rotate the tube, when in the electric field, is practically converted directly into light.

THE AMERICAN PROPOSALS WITH REGARD TO ELECTRICAL UNITS.

We have great pleasure in publishing the following letter from M. Guillaume, and a translation of the official report of his remarks at the recent meeting of the Société Internationale des Électriciens:—

"Dear Sir: The slight astonishment I felt on seeing my suggestions characterised as 'rather too nice' in the last issue of *The Electrician* was dissipated so soon as I was able to assure myself that they had been misunderstood. As a matter of fact, in all my remarks relating to terminology I only repeated—rigorously defining them—terms already employed for some little time in England in a very precise manner, some of which, if I mistake not, first saw light in your excellent journal. It is very fortunate that these words, created by English electricians, have an absolutely French root and termination [for instance, *reluctance* comes, no one can doubt it, from the French word *lutter*, formerly *lucter*], and we may hope that their form will, therefore, act as their passport, at any rate as much as it has done to words like *meeting* (pronounced *métingue*) and *square* (pronounced *skar*), with which our language has made the mistake of enriching itself.

"I send you, moreover, the text of my remarks, and I think that after you have looked at them, my proposals will seem 'rather reasonable' to you.—I am, Sir, yours truly,

"Ch. Ed. Guillaume.

"Bureau Internationale des Poids et des Mésures,
Paris, March 17, 1893."

[Translation.]

M. Guillaume: The American proposals may be divided into two categories. (1.) Definitions of new units and terms, and a unification of the vocabulary and notation. (2.) Sanction of the values of the legal standards. The first are within the competence of a Congress, the latter belongs to an official Conference. As regards the first, a Congress may come to a decision, as regards the latter, it can only express its wishes, of which, no doubt, a Conference or a diplomatic assembly would take cognisance, though only to the extent it deemed convenient. It will not be without advantage if we clarify our ideas on this question, either at the Congress, or, better still, by preliminary discussions.

The first thing to be done is to adopt a fixed rule for the termination of words denoting the same category of physical properties. For instance, *conductibility*, *malleability*, and *permeability*, are incontestably properties of certain substances, and are independent of the shape or amount. *Resistance* is a property of a conductor depending on its substance and shape. Speaking generally, the English have already adopted the words *conductance* and *permeance* the form of which is absobutely French, so that they will be neologisms for our language and not barbarisms like *self-induction*, *shunt*, *spot*, which have nevertheless been only too widely adopted in France. We should then have the following table:—

Properties of matter.		Values depending on the shape of a body.	
Resistibility.....	$[\alpha]$	Resistance ...	$[R]=[\alpha L^{-1}]$
Conductibility.....	$[\gamma]$	Conductance..	$[T]=[\gamma L]$
Permeability	$[\mu]$	Permeance ...	$[P]=[\mu L]$
Reluctibility	$[\rho]$	Reluctance ...	$[R]=[\rho L^{-1}]$

Hosted by Google

In the same way *inductibility** and *inductance*, though it would be convenient to define the meaning of the term induction, which is employed in very different senses. Two meanings would be suppressed by reserving the term *flux of force* for *total induction*, whilst *magnetic induction*, as generally understood, would logically mean *density of flux*, a term already employed. The word *conductance*, to which many electricians find it difficult to get accustomed, would simplify matters considerably; we should enunciate the well-known theorems, in fact, in the following way :—"The total resistance of a series circuit is equal to the sum of the resistances of the circuit." "The total conductance of a parallel circuit is equal to the sum of the conductances of the parallel circuit." The unit of conductance exists, it is the *mho*. Resistance will always have its *raison d'être* in science, but in commerce it is conductance which will become, in the case of distributing networks, the important magnitude; mhos, not ohms, will be spoken of one day in connection with distribution networks. The mhos of a circuit indicate its efficacy. A circuit of n mhos will allow n amperes per volt.

The American Institute has proposed a unit of magnetic field, the *gauss* $=10^8$ C.-G.-S. and a unit of flux of force the *weber* $=10^8$ C.-G.-S. These two units, unrealisable up to the present, only have their *raison d'être* because they form part of the coherent system already adopted. Such, indeed, was the reason for the adoption of the farad. The *weber per second* is a *volt*. But then there is no cause for adopting as the unit of magneto-motive force anything else than 10^8 C.-G.-S. units; since the magneto-motive force is equal to the field multiplied by a length, the unit of force should be the gauss centimetre, and not one-tenth C.-G.-S. If we sacrifice the C.-G.-S. system it should be in favour of the coherent system; another intermediary system would only confuse our ideas.

As regards material standards, I will call attention first of all to a misunderstanding in our Bulletin (p. 100). It is not a question of bringing the mass of silver deposited in the voltameter into relation with the gramme-weight, we can effectively compare by means of a balance the weight of the deposit with the standard weight, but it is a question of deducing the mass of the deposit, the value of g eliminating itself and the corrections for pressure, &c., being easily carried out. In fact, we obtain the mass without any correction by balancing the platinum cup with platinum, and weighing the deposit with silver weights (gilded or platinised).

Without wishing to discuss matters which are, as I have said, beyond the competence of the Congress, I may observe that after the Conference of 1884 the English retained the B.A.U., the Germans the Siemens Unit, and that in France we were divided between the legal ohm and the B.A.U. To-day the English give up the B.A.U., not merely as unit, but even as standard. The first proposal was, indeed, to define the new ohm as $\frac{1}{0{\cdot}9866}$ B.A.U. But after the Edinburgh Congress, to which foreigners were invited, the English unreservedly withdrew their standard, and now define the ohm as the resistance of a column of mercury of 106·3cm., &c. The German Bill just published contains the same proposal, and it is much to be desired that France should also adopt the new ohm. It is so approximately equal to the theoretical ohm, that instead of the B.A.U., the S.E. (Siemens'sche Einheit), the legal ohm and the true ohm, which are at present in existence, we shall only have for a long time to come a single ohm, at the same time true and legal—the 106·3 ohm. Later on, perhaps, there will be grounds for departing from this value, but only very special cases. The reform will be effected without anyone noticing it, since resistance-box makers have taken time by the forelock. The majority of the german-silver standards constructed of late years have been equal to or more than the 106·3. The adoption of the new ohm will be an excellent occasion to restandardise them.†

PARLIAMENTARY INTELLIGENCE.

HOUSE OF COMMONS—THURSDAY, MARCH 16TH.

Clapham Junction and Paddington Railway.

This Bill came before Sir John Kennaway's Committee of the House of Commons last week, when Mr. Pember, Q.C., and Mr. Freeman appeared as counsel for the promoters; Mr. Bidder, Q.C., and Mr. Courthope Monro for the Metropolitan District Railway Company; Mr. Littler, C.B., Q.C., and Mr. Wors ey Taylor, Q.C., for the Metropolitan Railway Company; Mr. Worsley Taylor, Q.C., and Mr. Claude Baggallay for the Commissioners of the Exhibition of 1851; Mr. Fletcher Moulton, Q.C., and the Hon. Sydney Holland for the Commissioners of Her Majesty's Works and Public Buildings; and Mr. Saunders, Q.C., and Mr. Lush Wilson for the City and Guilds of London Institute. There were also petitions against the Bill by the London County Council, the Corporation of the Hall of Arts and Sciences, the London and South-Western Railway Company, the Vestries of Chelsea, Paddington, and St. Margaret and St. John, Westminster, but no counsel appeared in support of the petitions.

Mr. PEMBER, Q.C. in opening the case for the Bill, explained that it would be an electric underground line from Clapham Junction, northward by Battersea Park across the Thames, through Chelsea and under Kensington Gardens to Paddington Station of the Great Western Railway, with a subway to the Albert Hall from the South Kensington Station. The capital of the Company would be £1,050,000, with £350,000 borrowing powers. The line would be made at a great depth below ground on the Greathead shield system, and the motive power would be electricity or cable, or any other means that the Board of Trade might sanction other than steam locomotive. Dealing with the petitions against the Bill he referred to that of the Commissioners of Her Majesty's Public Works and Buildings which alleged that the Royal College of Science included physical laboratories, astronomical observatories and other places for scientific research, and they were advised that if the railway was constructed and worked by electricity as projected, the work carried on at the College for public purposes and for the advancement of science would be seriously prejudiced. Serious disturbance would be caused to scientific instruments and appliances, to the detriment of the public service and the students, while the micrometer and photographic records made by astronomical telescopes, as well as observational astronomical work would be affected, and measurements of precision would be impossible. Commenting upon these allegations, Mr. Pember said if they were true he could only say that the life of London could not stand still even for astronomical and other scientific observations of a group of gentlemen who happened to live in the middle of it, and it would simply show that London was becoming unfit to carry on these delicate observations, and they must be carried on elsewhere. As a matter of fact, however, there was a complete answer to the whole case. After having referred to other potitions and to the probability of the financial success of the line, he called first

Mr. P. M. THORNTON, M.P. for Clapham, who spoke as to the inhabitants of that district desiring the line; Sir W. H. FLOWER, K.C.B., who, on behalf of the Natural History Museum, thought it would meet a public necessity; and Mr. H. A. HUNT, surveyor of Lord Cadogan, who also approved of it.

Mr. J. H. GREATHEAD, the engineer to the Company, then stated the objects of the Bill, and the course it proposed to take, stating that they proposed to have a generating station at Clapham, but the proposed generating station at South Kensington had been given up. The system employed would be the direct-current system. On the City and South London the pressure was 500 volts, but with an overhead conductor he thought the pressure might be increased; in fact, Lord Kelvin, who was one of the members of the Joint Committee of the two Houses who considered this question last year, recommended that by placing the conductor overhead instead of between the rails economy might be obtained by working with a higher potential. They proposed to insulate the currents completely, so that serious disturbance might be entirely avoided. He believed the speed would be 25 per cent. better than on the Inner Circle line, and that there would be ample traffic to make the line a financial success. In cross-examination he said that he did not know what was done within the walls of the College of Science and the City and Guilds Institute, but he did not think the vibrations from the tunnel would affect a microphone. He did not know of any electric railway in England working with the return conductor insulated, but he fancied there was a tramway at Buda-Pesth worked in that way. He was told there would be no difficulty in working with 1,000 volts, but he did not think they would attempt 2,000 volts; he admitted that the greater the potential the greater the danger of leakage. On the City and South London the leakage from the conductors amounted to something like half an ampere for the 6½ miles with 500 volts.

Lord CHARLES BRUCE, Chairman of the Royal College of Music, having given evidence that the accommodation which the line would give to the institution, was favouably regarded by the Committee of that institution,

Mr. CLARK SCOTTER, of the London and South-Western Railway, gave evidence in favour of the Bill, and spoke as to the traffic which his Company would be able to put upon the line.

H.R.H. the Duke of EDINBURGH, on behalf of the Exhibition Commissioners of 1851, expressed his opinion that the line was not only unobjectionable but was one of great importance, bringing the public from two great outlying railway centres, besides the advantage that it would be to the estate of the Exhibition Commissioners and to the Albert Hall. In cross-examination by Mr. Saunders, he said a lease had been granted to the City and Guilds of London Institute, and he would regard anything that prevented scientific education being given to the greatest possible advantage as a detriment to the people, in whom he was interested; but the question was one so simply professional and technical that he did not feel himself capable of dealing with it. From the mode of construction, and the depth at which it would be placed, he did not think it would be likely to cause any damage to the South Kensington institutions.

Mr. ALLEN SARLE, on behalf of the London, Brighton, and South Coast Railway, and Mr. HENRY LAMBERT, of the Great Western Company, having stated that the line was favourably regarded by their companies,

Prof. J. A. EWING, F.R.S., said that he had made a special study of electricity and its applications, as well as of earth tremors, for investigating which he had devised instruments. In conjunction with Mr. Preece he had made special experiments to test the amount and character of the disturbances caused by the South London line, with a view to determine how far they were due to preventible causes. Mechanical vibration would occur whether the train were worked by electricity or not, but magnetic disturbance would occur if the train were worked by electricity, while a third cause of disturbance would be that which proceeded from the electric currents used in the working of the line. In the case of an electric railway with a completely insulated system of going and returning conductors, the last cause of disturbance would not exist at all.

* The Report proposes to adopt the term *inductivity* as a synonym for permeability; one of the two would then play two parts. The latter, very convenient in practice, has, perhaps, the defect of recalling too exclusively a certain theory of magnetism.

† I should even see no disadvantage in keeping the name *legal ohm* for the new ohm, if for a year or two the figures 1893, or perhaps 106·3, are added in parenthesis. In this way we should avoid all confusion, and should not burden ourselves for the future with a new and useless word. On the other hand, the name *true ohm* could be retained for the *theoretical ohm*

Hosted by Google

Mr. PEMBER: As a matter of fact, with an earth current, if it is a question of a very delicate hyper-sensitive instrument being disturbed by a railway which passed along, say, within 100 yards or feet of it, it would not be free if the railroad passed within a quarter of a mile.

The WITNESS: It would not be entirely free. The disturbances which the City and South London gives rise to from this cause are felt even for miles through the passage of the current through the earth. The disturbance from earth currents was, however, quite preventible by the use of insulated return conductors, and would not be detectible by the most sensitive test that could be applied.

In cross-examination by Mr. MOULTON, the witness stated that one of the conductors on the City and South London line was insulated, and if the other were equally well insulated there would be no leakage into the ground of a kind to affect sensitive instruments.

A MEMBER of the COMMITTEE: If you had the other conductor insulated could you use the electricity again when it got back to the station?

The WITNESS: No, the energy is expended; it simply goes round in a closed system.

Does it return again? if so, that would look like perpetual motion.—It is rather difficult to give a categorical answer to that question on account of the fact that the circulation of electricity in the conducting system is different in its nature from the circulation of water in a tube. If the current has gone out on one of the conductors and done its work, and comes back along another, it has lost its energy.

But has it sufficient energy to go into the ground and cause disturbance?—That is coming back. It passes into the dynamo again.

Mr. MOULTON: Do you know that it was proved that in America there was not a single railway working with an insulated return?—I am not aware that there are in America any railways of the same kind as that which it is now proposed to construct. An insulated return becomes extremely easy in a tunnel railway. Continuing, he said that with regard to tramways, the practical difficulty in completing the metallic circuit was very great, but there was no practical difficulty in the use of a completely insulated system in a tunnel railway. The magnetic disturbance of delicate instruments was preventible partly by the proper arrangement of the motors upon the locomotives, and finally, if necessary, by the use of a compensating magnet.

Supposing these motors were put in improperly, or there were no proper compensating magnets, would not the Royal College of Science be interfered with?—I think the disturbance which I observed was of such a character that one reasonably could not complain of it as an interference, but if ever it were adjudged to be an interference it could be prevented by the device I have suggested. The simplest way to prevent disturbance by the current working the trains would be to have three conductors instead of two. If the positive conductor were arranged in a central position, and two conductors were arranged alongside of it, parallel to it as return conductors, those two sharing the work of returning the current between them, then there would be no effect outside the tunnel. As to the vibrations, he believed they might be felt in the Royal College of Science if means were taken by instruments of great delicacy to search for them; but he did not believe they would prejudice the work that was carried on in the College.

Mr. MOULTON: With regard to insulation, the return path of the electricity is made an easier one if you do not insulate the return, is it not; and, therefore, you would get more work out of your electricity if you let your insulation get out of order?

The WITNESS said to a small extent it would be so, but the question was too generally put. Inasmuch as any destruction of the insulation on the one conductor would probably also take place upon the other, there would be a cross leakage which would prevent them from getting so much work out of the electricity. The advantage which would be gained by the destruction of insulation would certainly not be enough to form a motive for deliberately destroying the insulation.

Before the Witness's cross-examination was concluded, by special permission of the Committee it was agreed that the evidence of

Mr. W. H. PREECE, F.R.S., President of the Institution of Electrical Engineers, should be interposed. He said that if the contention of the opponents were true that the disturbance must be felt and could not be remedied, it would negative any electric railway being carried out anywhere near London. The Central London Railway, which had been sanctioned, passed within three-quarters of a mile of the Royal College of Science, and that being passed without any protection the College was already subject to the danger apprehended from this railway—if it existed. He agreed that a return metallic circuit inside the tube would remedy any possible danger, and confirmed Prof. Ewing's views on that point. He could not say what the extra cost would be, but the intrinsic value of a second conductor could not be much more than probably £200 a mile.

Mr. SAUNDERS: With regard to the system of insulation, I suppose it could only be effected by the conductors being supported upon porcelain or china bearers.—Yes.

You cannot insulate the rail which is used for electric traction by means of encasing it in gutta-percha or anything of that sort?—Yes; I think the rails could rest on vulcanite.

But the conductor itself cannot be surrounded by that because it has to be touched by the brush and brought into physical contact, has it not?—It does not require to be surrounded, it only requires to be kept from the tube or from the earth.

A very slight accident, even with the best intentions on the part of the Company, might prevent it being effectual by carrying the current to the earth, might it not?—Carelessness, of course, might prevent its working, as would also dust or wet to a slight extent. He was not aware of any case where it had been tried and found to be successful.

In reply to the Hon. SYDNEY HOLLAND, the witness stated that a magnetic screen would prevent the magnetic disturbances from affecting the instruments at the Royal College of Science. The iron tubing of which the tunnel would be formed would of itself act as a screen to prevent the magnetic disturbance caused by the passing of the train from disturbing the instruments at the College of Science. He had not calculated the thickness of which the screen should be made.

Prof. EWING, in reply to the cross examination of Mr. Saunders, gave further evidence as to the results of his investigations into the disturbances caused by the City and South London line, but said that in the present case, if the precautions suggested were carried out, there would be no disturbance save of the most trifling mathematical character.

The Committee then adjourned till Friday.

FRIDAY, MARCH 17TH.

On the Commitee resuming, Mr. WILLIAM TROTTER, of the firm of Messrs. Capel and Trotter, stockbrokers, gave evidence as to the probabilities of raising the capital for the line; Lord SUDELEY, one of the promoters, spoke as to the probable remunerative character of the undertaking, and the large sources of traffic; Mr. ROBERT VIGERS, surveyor, gave estimates of the cost of land and property to be acquired; and Mr. C. S. PEACH, architect, who had devoted special attention to the subject of vibration, stated the results of his observations in connection with the City and South London line were that the ordinary road traffic produced more vibration than the underground electric railway.

Mr. PEMBER said the promoters were ready to submit to a clause which ought to meet all reasonable requirements in the following terms:—"In the event of the railway being worked by electricity, the following provisions shall have effect:—The Company shall use an insulated system of conductors for the conveyance of the electric current to and from the trains throughout the whole of their railway, and shall not permit the current, or any material part of the current, to be conveyed by the earth; the Company shall further construct and maintain their conductors and rolling stock in the way best calculated to avoid producing magnetic disturbance in the laboratories of the Royal College of Science and of the City and Guilds of London Institute; in the event of such disturbance occurring, it shall be open to the trustees (or managers) of these institutions to complain to the Board of Trade, and the Board of Trade may, after due inquiry into the character and extent of the disturbance, require the Company to take such additional precautions to mitigate the disturbance as the Board may deem expedient." He did not for a moment believe he would be able to satisfy the enthusiastic professors on the other side, and therefore he did not offer the clause to them, but to the Committee.

The CHAIRMAN: You put yourself entirely under the Board of Trade..

Mr. PEMBER: Yes, that is my offer to you, sir.

This concluded the case for the promoters, and

Mr. SAUNDERS addressed the Committee in support of the petition of the City and Guilds Institute and the Royal College of Science, stating that the whole existence of those institutions for all useful purposes depended upon the mode in which this matter was settled. As representing a scientific institution, and having to call before the Committee a professor of that institution (Prof. Ayrton), who had specially given himself up to the question of electrical technology, he did not propose to say a single word against electricity as a means of locomotion. He believed that electricity as a means of traction had a great future before it, and that the secret of the improvement of the means of communication in London was very much mixed up with electricity. But if electricity was to be used in connection with this railway the promoters had chosen the very worst possible route by bringing it in such close proximity to institutions where the most delicate electrical experiments were made with the most delicate instruments, which would have the effect of very materially interfering not only with the facility with which they were used, or the advantage with which they were used, but even with the use of them altogether. The case which he should present to the Committee was that there would be three distinct causes of disturbance anticipated from the construction of the railway, viz., the magnetic disturbance arising from the currents in the conductors, and from the leakage, which was the main disturbance, and mechanical vibration and the effect of the moving train.

Lord KELVIN was then examined by Mr. MOULTON, and said for many years he had given great attention to electricity and magnetism, and especially to electric screening. If the proposed railway had uninsulated conductors it would be absolutely ruinous to magnetic work in the City and Guilds Institute and the Royal College of Science, but the effect would be much less with perfectly insulated conductors.

Mr. MOULTON: Prof. Ewing has suggested that there should be one conductor outwards and two returns. Would you tell the Committee your opinion, as a practical man, of that device.

Lord KELVIN: If it were possible to maintain the insulation of all three conductors perfect, and to maintain the practical conductance through the two side conductors absolutely equal, then the disturbance due to the current through the line would be very much diminished indeed by the arrangement proposed by Prof. Ewing. He believed, however, that it would be almost impossible to maintain such a delicate balance. As to the iron tube of the line acting as a magnetic screen, it would do so very effectively if it were 7ft., or even 4ft. thick to a large extent, but it would not annul the disturbance. The effect of a 2in. thickness of tube as a magnetic screen would be practically *nil*. The arrangement of compensating magnets on the motors for the prevention of disturbance, in his opinion, could not be carried out. On the question of vibration, the witness described experiments which he had carried out, and said that he believed in a horizontal component of almost every vibration that they could have from disturbance, and that vibration would prevent the accurate reading of the electrical and magnetic instruments in use at South Kensington

Hosted by Google

In cross-examination by Mr. Freeman, Lord KELVIN said that at the various exhibitions at South Kensington there was considerable horse-power employed with various mechanical instruments, and also electrical generation, but he did not know if the electrical generation at all affected the conduct of the College of Science. The disturbance by electric currents, and by the effect of the electro-magnet of the motor, did not require any experiments to tell him that it would be very serious. As to vibrations, they could only be established by special experiments. It would be a very costly kind of experiment to place the railway there and then to find out that it did produce serious disturbance. He did not see any practical way whatever of annulling, or of seriously diminishing, the magnetic effects of the motors by counteracting magnets placed on the car, nor would an iron casing round the motors have sufficient effect to be f practical use.

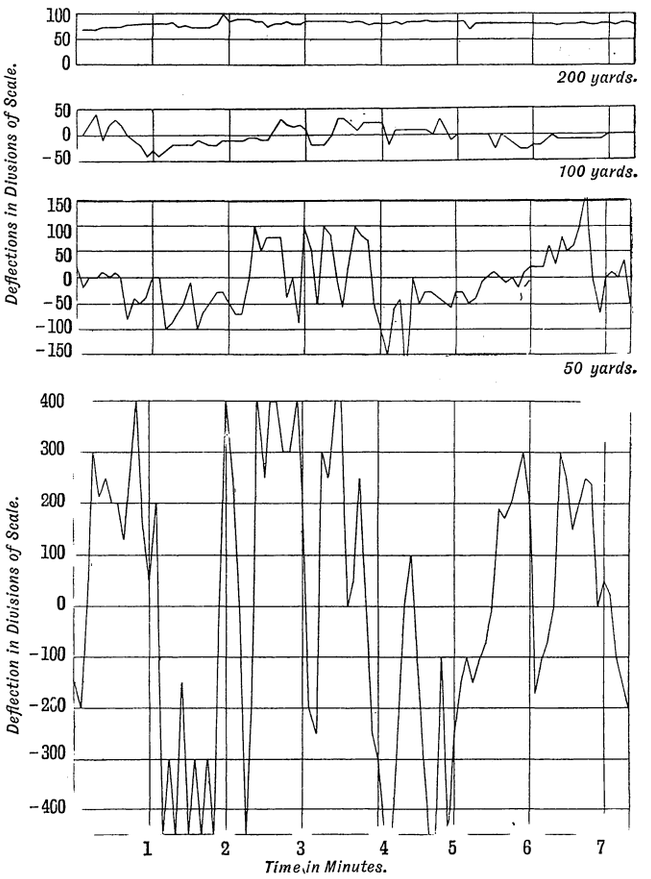
Re-examined by Mr. Moulton, Lord KELVIN, speaking of Prof. Ewing's suggestion of having two return conductors, said that if a bit of paper, or anything of the kind got between the brush and the conductor it would for the time destroy the balance. He did not say that it would be impossible to keep the balance by proper arrangements, but it would be necessary that the conductance of the two should be very exactly equal, and should be always equal and perpetually kept equal

Sir WM. PRIDEAUX, Clerk to the Goldsmiths' Company, who for some years acted as hon. sec. to the City Guilds, produced the Articles of Association of the Institute, showing the educational and technological character of the institution, and gave evidence as to the expenditure which had been made upon it. When the South Kensington and Paddington Subway was first proposed, Lord Sudeley and the promoters met the Council, when it was agreed that a clause should be introduced into the Bill stating that electric traction was only to be resorted to and used with the approval of the Council and of Her Majesty's First Commissioner of Works for the time being, both being unanimous. The Council never conceded that the proposed railway should be worked by electrical traction. That scheme was abandoned.

Prof. W. E. AYRTON said that for the last 25 years he had been profes sionally engaged in connection with the industrial application of electricity. In the early days of electric traction eight or nine years ago, he devoted a good deal of time specially to the development of overhead electric traction, and was in entire agreement with the application of electricity as a means of locomotion. He was, therefore, very sorry to have to oppose this Bill, but at the same time, if passed, it would certainly damage two very important teaching institutions in London, so he felt that he had no alternative but in the interests of science to oppose this particular application. The researches at the Central Institution were not conducted for the entertainment of the professors, but for the instruction of students. He was personally engaged in training men to become electrical engineers, but there were also students being trained to become mechanical engineers, civil engineers and chemical engineers. In all those branches the students were taught the mode of using electrical instruments, so that they might have a fair working knowledge of the commercial uses of electricity. The foundations for the delicate instruments in use were put 6ft. below the floor of the basement, or 16ft. or 17ft. below the street level, in order to avoid disturbances from the street traffic. The foundations, therefore, would not be far from the level of the proposed railway and it was difficult to say whether under those circumstances the railway might not mechanically disturb them. Had they known they were to have the disturbance of burrowing underneath, they would not have gone down to avoid the street traffic disturbances. The mechanical evil, however, would not be nearly as serious as the magnetic disturbance. He produced illustrations (*see* curves) of the disturbance caused in the neighbourhood of the City and South London line, taken by the employment of a portable magnetometer. At 200 yards distance they would get a little disturbance, but at 300 yards for the students' ordinary work (not speaking of the most delicate research), he did not think they would object to the railway. The use of a single insulated return on the line as at present laid out would not protect them from disburbance. Prof. Ewing's suggestion for two insulated returns was a very pretty one, but rather crude. He had himself thought of many suggestions that could he devised for screening magnetic disturbance produced by an electric railway, which were as pretty as that of Prof. Ewing's on paper, and about as unpractical. Any one of those conductors must carry a large current. The current going out of the City and South London, for instance, was about 900 amperes, and any one of the conductors alone would produce enormous disturbance. Now, the promoters proposed to put six conductors so mathematically exact in the tunnels, and they were going to send the current through those conductors so exactly and to regulate the currents and the resistance of the conductors so exactly, that no disturbance would be produced! He had made calculations that if five per cent. of the current preferred to come back by one of the return conductors instead of by the other, with the railway forty feet distant from the laboratory, they would have a disturbance of about thirty-seven deflections. If Prof. Ewing would consent to spend the rest of his life forty-five feet below the Exhibition-road, always regulating the conductors and the current flowing along them, he might attain success; but it was absolutely certain that the ordinary man who looked after an electric railway would never be able to attain success.

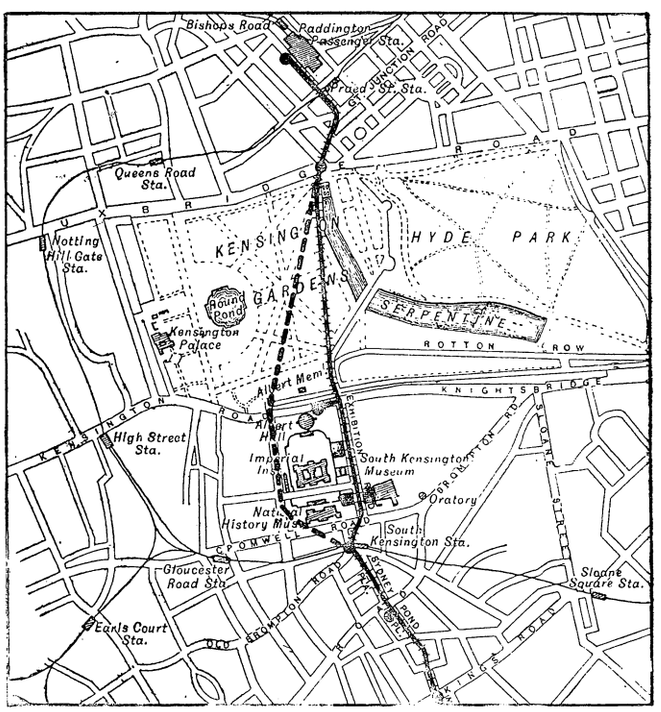
Mr. SAUNDERS: In fact, Prof. Ewing's suggestion is theoretically correct, but practically impossible.

The WITNESS: It is theoretically perfect, but practically impossible. He agreed with Lord Kelvin that it was necessary to have perfect insulation, but, what was much more difficult, they must have the same resistance for each of the return conductors. If one got a little hotter than the other, or wore more than the other, if the brushes of the passing trains made worse contact with one conductor than with the other, then the balance would be destroyed. It was the practice on all electric railways or tramways that he was connected with to use simply the rails and the earth as the returns. Though it was said there was a case at Buda-Pesth where a single insulated conductor had been tried, he did not know it, but to use six insulated conductors, and to make those experiments while the railway was running, at the expense of the laboratories of the City and Guilds Institute and the Royal College of Science, seemed to him to be very



Taken in Prince's-square, 25 yards from centre of Kennington-park-road March 3, 1893. Magnetometer, E. and W. Period = 10 seconds.

[The magnetometer appears, therefore, to have been placed at an angle of about 60° with the line of the railway. We have no information as to the value of the deflections.—Ed. *E.*]



——— Projected route of Railway, according to plan issued by the promoters in January, 1893.

- - - - - - - - - - - - - - Deviation proposed by Prof. Ayrton.

Hosted by Google

serious. As far as economy was concerned, it would be to the interest of the railway to let the return current go to earth in as many places as possible. They would want to keep the going conductor well insulated and the others as badly insulated as possible, in order to diminish the total resistance of the circuit. As regards the clause suggested by Mr. Pember, it would be an impossibility for the Board of Trade to enforce precautions. He had made experiments as to the magnetic screening of an iron tube, and while he thought a tube 15 inches thick would have some screening effect, with one of two inches there would be practically no screening whatever. When the Inventions Exhibition was held, the generating plant was some hundred feet from the laboratories, but the main reason for their getting no disturbing effect was that they did not commence their work at the Institution practically till after the reign of the Exhibition. As to Mr. Peach's experiments with regard to vibration, they were most unsatisfactory, as the instrument which he used would not record any horizontal vibration at all, and he did not think it would be very sensitive to vertical vibration.

In cross-examination by Mr. FREEMAN, the witness stated that if the railway was 300 yards away (*see* Map), in the interests of applied electricity he should not think it desirable to oppose it, but even if they did not use an insulated return there it would not be nearly as serious as a line under the Exhibition-road. A line with two conductors perfectly insulated would do far more harm at 25 yards distance than an ordinary uninsulated return at 300 yards distance. Asked if he had ever made experiments in the process of insulating three conductors as suggested by Prof. Ewing, the witness stated that he knew a case where three conductors were used, not in connection with an electric railway, but for the transmission of power at Frankfort. It was proved mathematically that the current going by one conductor divided itself between the other two, and therefore at some distance from the three conductors, it would be apparently impossible to detect the magnetic disturbance. However, some of the German Government officials and himself, believing that it existed, went to find it, and they did find it, showing that it was very difficult to attain such a condition of absolute non-magnetic disturbance with three conductors at a considerable distance —at a far greater distance than there would be between the proposed railway and the Central Institution. The disturbance arising from the inequality of the current upon the return conductors and of the rubbing contact might be diminished, no doubt, by frequent crossing sections.

The Committee then adjourned till Monday.

MONDAY, MARCH 20TH.

Prof. W. E. AYRTON was recalled and gave further evidence in regard to the vibration caused by the trains on the City and South London line which he had observed since his examination on Friday. He said that, standing on the platform, the vibration could be distinctly felt with the feet or with a walking-stick, and putting his hand upon the signal-box, the firm wooden supports, and, indeed, the whole box, could be felt to shake, and the windows were made to rattle even, by the moving of the train in the other tunnel. Therefore, it would not require any delicate instruments to convince him that the vibration would have a serious effect upon the galvanometers and other instruments used at South Kensington. The engines and dynamos which were in use at the College were at the extreme end, away from the delicate instruments, and were ridiculously small compared with what would be used on the railway. The railway would have two machines, one at Clapham Junction, which would convert the mechanical power into electrical power, which would be sent by the insulated conductors ; and there would be a similar machine on the locomotives of the trains, which would convert back again the electric power into mechanical power, so that the moving train would bring within 40ft. of them large powerful electro-motors, which he felt sure would produce very serious disturbance.

The WITNESS was cross examined by Mr. PEMBER as to whether the vibration of the signal-box and the rattling of the windows was not caused by the rush of air through the tunnel. With regard to the use of triple conductors for the avoidance of magnetic disturbance, the witness stated that it was more a question of practice than of theory, but there was one theoretical question which ought not to be forgotten, namely, that they could not arrange three conductors to produce no magnetic disturbance anywhere, but could only arrange the carrying of definite currents so as to produce no magnetic disturbance at a particular place. So that even if it were possible to carry out the conditions of placing three conductors in a tube carrying different currents, and there were absolutely no magnetic disturbance at one place, at other parts of the same building there would be magnetic disturbance.

Mr. PEMBER : Have you calculated at the nearest point of your laboratory what the effect of 5 per cent. of inequality on the part of the return conductors would be, comparing it with the ordinary magnetic action of the earth. I am told it would be only one seven-thousandth part of the earth's magnetic force at the nearest point, and that at most parts of the laboratory it would be less than one twenty-thousandth part.

The WITNESS : Supposing it is one seven-thousandth, that may be a large quantity, because there are certain experiments where the earth's field would interfere with us very much, and therefore a fraction of the earth's field may interfere with us. A changing field equal to the earth's field would interfere with us, but a stationary field like the earth would not interfere with us. If only one train per day will run I should not mind, but they will be running every two or three minutes.

In reply to the CHAIRMAN, the witness reiterated his conviction that neither cross connections, triple-insulated conductors, nor compensating magnets would entirely remedy the disturbance, while the tubing of the tunnel would have to be extremely thick for it to act as a magnetic screen. To have an outer and inner tube with the space between packed even with iron would not be so effectual as a solid iron tube of less thickness.

Prof. NORMAN LOCKYER was then examined by Mr. Moulton on behalf of the Royal College of Science, and described the scientific work carried on at that institution which he regarded as of national importance. Some millions of money had been spent in connection with the College, and the Governors had recently invested another £100,000 for the purpose of increased laboratories, and for the housing of the delicate apparatus which was used for instruction of the students and in connection with their practical work. It would be quite impossible to carry on their work if the railway were to come there.

Prof. A. W. RÜCKER, Professor of Physics at the Royal College of Science, gave similar evidence. Even accepting the proposition that 5 per cent. of inequality in the work of the return conductors would be equal to one seven-thousandth or one twenty-thousandth of the general magnetic force of the earth, he would regard that as serious, though the effect might be largely diminished by the use of cross connection.

Mr. PEMBER : Are not the natural variations from day to day in terrestrial magnetism greater than that difference of one seven-thousandth or one twenty-thousandth ?—Yes, they are during the whole day.

And a professor tells me that you may take them as being fifty times as great ?—I am not able off-hand to say what the maximum is.

In re-examination by Mr. MOULTON, he said the average diurnal variation in the terrestrial magnetism was spread slowly over the whole twenty-four hours, and would affect no individual reading. It was not at all comparable with the disturbances which would be caused by the electric railway.

Mr. C. V. BOYS, Assistant Professor of Physics at the Royal College of Science, speaking with reference to the suggested double return conductors, said that while it certainly seemed on paper a most excellent scheme, and one which, if the enormous counter effects exactly balanced one another, would be an advantageous scheme, yet as a scientific man and not an engineer, he would expect such a suggestion if he had made it to be received by a practical engineer with ridicule. Engineers always found difficulties that the professors could not foresee. If it succeeded the Company would benefit by it, but if it failed the college would suffer. As to compensating magnets or dynamos he did not consider it a practical suggestion. As to shielding the car and motors by a screen, dealing with the car first, if they attempted to put an iron shield outside it, it would be made so much bigger, and in consequence so much worse. To shield the motor would increase the weight of the whole thing very greatly indeed, and they could not by a compensating magnet shield the magnetism of the motor.

In cross-examination by Mr. FREEMAN, he said that insulation alone, even of the most perfect character, would not obviate the evils which he feared of interference with the instruments. A large effect might depend upon there being a going and returning current at a distance from one another, in which there is no leakage at all. If Prof. Ewing's scheme were successfully carried out, and a balance were successfully obtained (a point on which he would not like to offer an opinion), then all magnetic disturbance due to the mains, the mere conductors going and returning, would be obviated for the particular distance at which the balance was complete ; there would be no disturbance there, but there would be disturbance at other places. In the physical laboratories they were more afraid of the magnetic disturbance than of the mechanical disturbance. There were large engines at work at South Kensington Museum, but they did not cause any serious disturbance.

Mr. MOULTON stated that Prof. Huxley would have given evidence, but was too unwell to attend, and Sir Henry Roscoe could also speak to the importance of the work at the Royal College of Science.

The CHAIRMAN said they need not trouble to call Sir Henry Roscoe.

Mr. WILFRED AIRY, C.E., who had had large experience in matters of vibration, spoke as to the vibration experienced in connection with the City and South London line, and said that he did not think the spring machine used by the promoters' witnesses for testing the vibration was a reliable instrument.

This being the whole of the evidence, Mr. Moulton addressed the Committee for the Royal College of Science, Mr. Littler for the Metropolitan Railway Company, Mr. Bidder for the Metropolitan District Company, and Mr. Pember was then heard in reply.

The Committee then consulted for a short time in private, and upon the re-admission of the counsel and parties

The CHAIRMAN stated that the Committee were of opinion that the preamble of the Bill was not proved, and the Bill was therefore rejected.

The promoters of the Clapham Junction and Paddington Railway did not apply yesterday, as announced, to the Select Committee who rejected the scheme on Monday last for their consent to a motion being made in the House for the re-committal of the Bill to the same Committee with a view to placing before them a proposal intended to satisfy the opposition of the City Guilds Institute and the Royal College of Science. The proposal was that the use of electricity should be restricted to within a certain distance of these buildings—that is to say, that the trains when passing these institutions shall be propelled by some mechanical contrivance other than electricity. The non-application for re-committal of the Bill does not mean that one may not be made after Easter. We were informed yesterday that the differences of the promoters with the authorities of the College of Science have been practically settled.

The National Telephone Company and the Salford Tramways.

The Salford Improvement Bill, which came before a Committee of the House of Lords on Thursday last week, the Earl Cadogan presiding, contained a clause to double the tramway along the Eccles road, and was opposed by the National Telephone Company, who alleged that the electrical working of the lines would derange their system. Mr. Balfour Browne appeared for the Corporation, and Mr. Pember for the Telephone Company.

Hosted by Google

Mr. BALFOUR BROWNE characterised the petition of the Telephone Company as an impertinent one, and urged that they had no more right to the earth as a conductor than other people; but to save expense they trusted to earth returns for their telephonic communication. At the present time, with the single line, the Corporation had power to use electricity without the Telephone Company having any protective clause against them, and all that they proposed to do was to double the line for the benefit of the public.

Mr. CORBETT, the borough engineer, was called, and proved the necessity for widening the line, and was cross-examined by Mr. Pember as to clauses which the Telephone Company had obtained in the case of other electrical tramway Bills, but the witness admitted his ignorance on that subject.

Mr. PEMBER then addressed the Committee, stating that in the case of the Birmingham Central Tramways case in 1891, the Duke of Westminster's Committee gave the Company a clause with which he would be content in the present case. At Birmingham the Tramway Company had powers to work by electricity all along, and when they came for a small extension the Committee gave the Telephone Company protection in respect of the whole system of tramways. The clause which he proposed should be inserted in the Bill was as follows:—

"For the protection of the National Telephone Company (Limited), its successors and assigns (in this section called the Telephone Company), the following provisions shall have effect in the event of any tramways of the Company being worked by electricity, otherwise than by electrical power carried along with the carriages, that is to say—

(1.) The Company shall so construct their electric circuits and other works of all descriptions, and shall so work their tramway in all respects as to prevent any injurious interference by induction or otherwise with the electric circuits from time to time used or intended to be used by the Telephone Company for the purpose of telephonic communication, or with the currents in such circuits, provided that, as regards electric circuits erected or laid down by the Telephone Company after the construction of the works of the Company, this sub-section shall only apply if reasonable and proper precautions have been taken in the erection or laying down of such circuits, and if they have not been erected or laid down in unreasonably close proximity to the lines or works of the Company.

(2.) Seven days before commencing to lay down any electric line, or to supply electricity through any line, in any manner whereby the work of telephonic communication through any wires or lines belonging to the Telephone Company and lawfully laid down or placed in any position by them may be injuriously affected, the Company shall, unless otherwise agreed with the Telephone Company, give to that Company notice in writing specifying the course, nature, and gauge of such electric line, and the amount and nature of the current intended to be sent along the same, and the Company shall conform with such reasonable requirements as may from time to time be made by the Telephone Company for the purpose of preventing the communication through such wires or lines from being injuriously affected as aforesaid.

(3.) If any difference arises between the Company and the Telephone Company with respect to anything in this section contained, such difference shall be determined by the Board of Trade, whose decision shall be final, and sections 30 to 32, both inclusive, of the Regulations of Railways Act 1868, shall apply in like manner, as if the Company and the Telephone Company were companies within the meaning of that Act.

(4.) Nothing in this section shall apply to repairs or renewals of any electric line so long as the course, nature, and gauge of such electric line, and the amount and nature of the current sent along the same, are not altered.

Mr. WINTERBOTHAM, solicitor to the Company, stated that a protective clause had been obtained in about 50 cases, and the Birmingham clause was even more stringent than that now proposed, but they had only been fought in 10 cases out of the 50.

Lord KELVIN gave evidence as to the disturbance caused to the telephone lines by the working of electric tramways, and said that the twin wire would greatly increase the cost of the Telephone Company. The telephone electric currents going to earth would not act detrimentally to electric tramways or electric-lighting companies.

Mr. BALFOUR BROWNE addressed the Committee, asking them to give the powers asked for, without the protective clause to the Telephone Company, but after a private consultation,

The CHAIRMAN announced that the portion of the preamble of the Bill relating to tramways was proved; but they required that a clause should be inserted for the protection of the Telephone Company, and in reply to Mr. Balfour Browne, said that it was intended to apply to the whole of the tramways.

Mr. BALFOUR BROWNE urged that the clause ought not to apply retrospectively. If the Telephone Company wanted such protection they should themselves introduce a Bill for the purpose. The Corporation of Salford rather than have a clause of that nature put upon them, would withdraw the tramway powers from the Bill, for it would put them under a serious obligation involving, he believed, thousands and thousands of pounds expenditure.

That part of the Bill relating to tramways was, therefore, withdrawn.

Edgware Road and Victoria Railway.

Owing to the pressure on our space, we are compelled to hold over our report of the proceedings in Committee in connection with this Railway Bill until our next issue.

Waterloo and City Railway.

On Tuesday last the Bill for the construction of an electric railway between Waterloo and the Mansion House, which was brought in last Session, was proceeded with before Sir Charles Dalrymple's Committee.

Mr. Pember, Q.C., Mr. Bidder, Q.C., and Mr. Ackworth appeared as counsel for the promoters, and the only opponents were those who desired protective clauses, among them being the London County Council and Mr. Walter, proprietor of *The Times*.

Mr. PEMBER, in opening the case for the Bill, said that it was practically opposed on preamble, the time which had elapsed having given them opportunities to make arrangements with the opposition. The scheme was a very simple one, being to construct a line 1½ mile long at an estimated cost of £610,000, starting from Waterloo Station, passing along Stamford-street, crossing beneath the Thames at Blackfriars, and thence, by way of Queen Victoria-street, to the Mansion House, at depths varying from 15½ft. to 96ft. below the surface of the streets. It was not intended that there should be any stations *en route*, but merely the terminal stations at Waterloo and the Mansion House, the object principally being to afford passengers to Waterloo an access to the City.

Mr. GREATHEAD, the engineer to the line, gave a description of its character and the method of construction, and Mr. SCOTTER, general manager of the London and South-Western Company, gave evidence of the convenience which it would be to passengers travelling by that line desiring to reach the City, and said the proposal was so favourably regarded by his Company that they would be willing to enter into a working agreement with the proposed new Company.

The Committee then formally declared the preamble of the Bill proved, and proceeded to adjust its clauses, and finally ordered the Bill to be reported to the House for third reading.

Baker-street and Waterloo Railway.

On Thursday last week this Bill came up in the House of Commons for consideration of the Lords' amendments, which were agreed to.

Barry Electric Railway.

The Barry Railway Bill, which empowers the Company to construct new dock, railways and tramways to be worked by electricity, and to raise £480,000 further capital, with £160,000 borrowing powers, came before Mr. Mellor's Committee on Wednesday last as an unopposed measure, and was ordered to be reported for third reading.

Brighton and Rottingdean Seashore Railway.

In the House of Commons on Tuesday last, the Brighton and Rottingdean Seashore Electric Railway Bill was read a second time.

BOOKS, &c., RECEIVED.

SPECIAL NOTICE.

With this issue of "THE ELECTRICIAN" is published (Gratis to Subscribers) a fine Steel-Plate Portrait of the late Dr. WERNER VON SIEMENS.

Complaints of non-receipt should be at once sent to "The Publisher."

GOOD-FRIDAY WEEK.

"THE ELECTRICIAN" will be published on THURSDAY in Good Friday week instead of Friday. Communications intended for this issue must reach us not later than Wednesday Morning's post.

Alterations to existing Advertisements and copy for new Advertisements should reach the Publisher on Tuesday, but in any case not later than Wednesday mid day.

ELECTRIC RAILWAYS AND ELECTRICAL DISTURBANCES.

Well may the promoters of the Clapham Junction and Paddington Railway exclaim that they have been wounded in the house of their friends. After three days' costly combat in Committee it was decided, mainly at the instance of Prof. AYRTON, that the preamble of the Bill was not proved. From an electrical-engineering point of view this defeat is to be regretted; we were promised 1000-volt and insulated-return working, both interesting departures from ordinary practice. From the investing and travelling public point of view the deferment of the line for at least another twelve months is also perhaps a matter of regret. On the other hand it is impossible not to sympathise with those in charge of the scientific institutions threatened with earth-currents, magnetic-storms, and anything but harmonic mechanical vibrations. For our own part, we are inclined to believe that the resources of electrical and mechanical engineering would not have been unduly strained in the endeavour to obviate all cause of professorial complaint; but, of course, an ounce of actual experiment is worth a pound of pious belief in matters like this, and it was only natural that Prof. AYRTON and his colleagues should dislike the experiment being made at their expense. Under the circumstances, the promoters would have been well advised if they had consented betimes to a reasonable deviation of trace as well as to the clause rendering them liable for any disturbance which might arise from the operation of the line. Two courses are open to the promoters; the one to sacrifice the present Bill and to introduce another next year, taking the route shown in the map which will be found in another column the other to work the whole or part of the line by cable. It appears

Hosted by Google

that Prof. AYRTON would not object to a line constructed *with as little care for leakage* as the City and South London line, if only it went up Queen's Gate. We are inclined to doubt the policy of such a concession. In any case, the South Kensington Laboratories seem to have gained a victory, though at the expense of a good deal of personal feeling and contradictory evidence.

We may now turn our attention to the much wider, and in many respects graver, question of the probable effect of the more important electric railways which have been projected, and which were fully described in our issue of January 13th. And not only to these, but to the working of the Metropolitan and District railways of London by electricity—the solution of which problem every electrical engineer looks forward to as a crowning achievement of the expiring century.

Mr. PREECE recently remarked that the earth currents generated by the City and South London Railway had so disturbed the telegraph instruments on the Continental cable circuits at North Walsham, 130 miles from London, that the passage of every train between the City and Clapham could be checked. But this would only mean that a difference of potential was set up at the London end of the circuit, and, similarly, a waistcoat-pocket battery could cause "serious disturbances" at the other end of an Atlantic cable. Prof. AYRTON does not appear to have been alarmed by earth currents, because he has no long wires by which these might be picked up, and disregarding the earth-current question, he considered magnetic disturbances only. It seems, however, very probable that the greater part, if not practically the whole, of the disturbances recorded by him, were due to the magnetic effect of these very earth currents, which, as the City and South London line is at present constructed, are far more serious than is generally supposed. A railway of this kind with a single conductor is, like a telephone service with one wire, only half built; there can be no excuse beyond that of expense, for using a single conductor and an earth return. The practice is likely to cause a very serious nuisance, on the one hand to the Telephone Company, on whom no sympathy need be wasted, and on the other, to every householder in the district, whether he is in the habit of using magnetometers or no.

On Wednesday last we paid a visit to No. 156, Clapham-road, where a Mr. GLEW carries on the business of chemist and druggist close by the electric railway. Some two years ago Mr. GLEW, who takes great interest in electrical matters, tested his gas and water pipes, and found evidence of strong earth currents. He has for some time past exhibited in his window a simple galvanometer which is strongly deflected, and is always in motion while the trains are running. An ordinary electric bell rings distinctly when connected in the same manner between the gas and the water pipes. The difference of potential has been measured, and is found to be about $\frac{1}{3}$ volt. The effect is less in wet weather than in dry. Even Mr. HARNESS is well aware, when he humanely sells belts without connections, that where there is current there must be corrosion, and as the current in a single house in Clapham-road far exceeds anything that could be generated by a cart-load of belts, the corrosion that must be going on must eventually do more harm than it has done to the whole of Mr. HARNESS's deluded patients. The remedy is so obvious that this part of the subject may be dismissed. But Mr. GLEW has experimented also with an ingenious little reflecting magnetometer, and he finds that when the needle is set by a control magnet (the shop scissors) so that it is approximately at right angles to the railway, hardly any disturbance is observed; when, set parallel to it, however, considerable deflections are observed. This experiment has been repeated with more elaborate appliances by Prof. EWING, and points to the currents and not to the stray field of the motors or to moving masses of iron as the disturbing cause. The iron tunnel, in fact, seems to have no screening effect at all, but is merely a huge uninsulated conductor. The effect of a pair of fairly-insulated conductors leaking only an ampere or so to the mile, and enclosed in and insulated from, and screened by, an iron tunnel, has yet to be tried. It is greatly to be regretted that the City and South London Railway Company were not better advised in this respect from the first. Meanwhile, no experiments and evidence about the behaviour of an iron tunnel, which itself vainly attempts to conduct the return current, are of much use in settling the real question of the disturbances which might be set up by a properly-fitted line. We understand that some attempt has been made to mend matters by a good metallic connection between the sections of the tunnel which are broken at each station; but this is a trifling matter compared with the reasonable precaution of an insulated return. The *raison d'être* of an insulated return is, we may remark in passing, rather difficult to make clear to the uninitiated, but it is a severe strain upon the gravity of a witness to be asked whether its advantage does not consist in the fact that it renders "the electricity" available for further use—after the manner of the oil-circulating arrangements now so common in our central stations. We can almost imagine one well-known electrical joker gravely replying that the insulated return is in a way a disadvantage, inasmuch as "the electricity" is *filtered* by its return through the earth to the generator.

Turning now to the probable nature of the dreaded disturbances other than those due to earth currents, we suppose they are of three kinds—mechanical vibrations, the movement of stray fields of motors, and the variation of the magnetic field due to the permanent conductors. The mechanical vibrations, together with the noise inside the tunnel which is a rather objectionable feature of the South London line, could be greatly reduced by suitable modifications of the permanent way, as on certain portions of the Metropolitan line. The stray field of the motors is of two kinds, the one passive, due merely to the movement of masses of iron. An iron tube is the best possible shield in such cases, but the thickness necessary to quench the effect is difficult to determine. Disturbances of this kind were noticed, it is true, during the original experiments for the determination of the ohm at King's College in 1863, and were due to the passing of iron steamers in the Thames, but in those days the Embankment was not built, and as a matter of fact, the experiments were conducted in a basement room overlooking the river, steamers passing within a few feet of the apparatus. We understand that not only is no such disturbance felt in the present laboratories, either from ships or from the trains on the Metropolitan Railway, but the vibrations caused by the latter are insignificant compared with the tremors due to the street traffic in the Strand. A far more serious, but perhaps more easily cured, disturbance is that due to the stray fields of the motors. Much misplaced ingenuity has been spent in the design of "ironclad" dynamos, in the belief that a stray field means stray energy and low efficiency. An ironclad machine saves a very few ampere-turns, generally at the cost of ventilation and accessibility. Without, then, disparaging the design of the motors used on the City and South London line, we have no hesitation in expressing the opinion that their stray field at some little distance is probably greater than that of any other type. If it were worth while, this stray field could be reduced to a very small amount.

Hosted by Google

Messrs. Edser and Stansfield measured the stray fields of a number of machines last year, and by far the greatest effect was produced by an Elwell-Parker dynamotor; and yet such a machine, weighing over seven tons and fixed about sixty feet away from the Millard Laboratory at Oxford, is effectually and completely screened by a layer of nine inches of scrap iron between a brick wall seven feet high, and an inner wall of one-inch boards. The field due to the current in the permanent conductors could be neutralised in several ways. One, a double return, was suggested in evidence before the Committee. Another way would be to wind a few back turns of wire round the unhappy laboratory itself in a plane at right angles to the intruding lines of force. This winding should be connected with the offending conductors, and whatever current they might carry, and in whatever direction, the stray field would thus be automatically cancelled.

REVIEWS.

Transformers: Their Theory, Construction, and Application, Simplified. By Caryl D. Haskins. (Bubier Publishing Company, Lynn, Mass; and E. and F. N. Spon, London, 1892.)

This is a praiseworthy effort to produce a semi-technical yet semi-popular book on the subject of the alternate-current transformer. There is much in it that is good, clear, and even suggestive, marred, indeed, by occasional faults of style or of abstract science, but still useful to the general electrical reader or to the engineer who wants to know something about transformers. Beginning with the notion of the magnetic field surrounding an electric current, and of its propagation outward from the wire, the author at once introduces the notions of Faraday about induction of electromotive forces in conductors in varying fields, and explains in very simple language the fundamental ideas about alternate-currents. The attempt to explain popularly (on page 39) the choking action of self-induction is bold rather than successful. The second chapter winds up with some general ideas about eddy-currents, hysteresis, and magnetic leakage. The third chapter gives the theory in the Hopkinson form. The fourth professes to deal with the evolution of the transformer, but omits all mention of Joseph Henry, of Bachhofner, of Ritchie, and of Sturgeon; and jumps from Faraday to Ruhmkorff, and thence to Jablochkoff and Gaulard. The fifth chapter is on construction, and contains some useful notes respecting American practice, concluding with practical hints. In the sixth chapter, on the transformer in service, there are also some useful hints; but the descriptions of modes of arranging transformers, including an incorrect three-wire plan, which the author rightly condemns, are not all true descriptions of the practice as found in England. Chapter seven describes a number of commercial forms. The seven short appendices relate to high voltages, the welding machine, constant-current transformers, and other topics.

As to the points that seem to us faulty, they can easily be amended in a second edition. We were not aware that the Greeks christened the effect of friction on amber "electron," or that the effect of friction had anything to do with the Greek name of the substance. We were under the impression that the term "Converter" for transformer was invented by Mr. Westinghouse, and that the use of that term was almost exclusively confined to America. The author, however, tells us that it is called converter, "especially in Europe." There is nothing like going abroad for information about ourselves. The old untruth that electricity always takes "the path of least resistance" is trotted out to prove that magnetic lines always do the same thing. If they did do so why should there ever be any magnetic leakage into by-paths of greater resistance? If spelling with capitals is any clue to meaning, one would suspect the author to be in doubt whether parasitic induced currents were discovered by Prof. Foucault or by Prof. Eddy. Of course he knows better himself. He omits to mention on page 51 how complete a remedy against eddy-current losses in the copper is afforded by stranding the conductor. An author who states that "in Europe it is the general practice to install them (the transformers) *within* the building whose lighting service they are to maintain" must beware of the wrath of Mr. Musgrave Heaphy and of all the fire-insurance offices. His recommendation on page 103, that the transformers should be placed "when out of doors, either on the side of the building, or still better, *upon a pole* when available" is not explicit enough. He ought really to say whether a north pole or a south pole is the more suitable; otherwise we poor Londoners who have no other sort of pole "available," might be in doubt. Perhaps, like Mr. Crompton in the fervid words of the newspaper reporter, we might prefer to erect the apparatus upon the horizontal component of the earth's magnetism. If Mr. Haskins will acquaint himself with European practice as it is, and not write of it as it is only supposed to be, he will make his book of more use to English readers. The very success of those parts which describe American practice leads us to think him capable of yet higher efforts; and we welcome him into the field of electrical literature.

The Practical Management of Dynamos and Motors. By F. B. Crocker and S. S. Wheeler, D.Sc. (London: E. and F. N. Spon.)

The contents of this little book appeared as a series of articles in the *Electrical Engineer* of New York, between September, 1891, and May, 1892. Its object is to give simple directions for the practical use and management of dynamos and motors, both during runs and at breakdowns. Admittedly incomplete, this work forms but the skeleton of a larger and more elaborate treatise on the subject. The first three chapters are introductory, and are designed to teach those who do not know what a dynamo is. The remark that "fine finish" on a machine causes it to receive much better treatment than if of good but "unfinished" construction, is worthy of consideration. Well finished fittings on a machine cost something, but one is satisfied if their inspiring presence guards the machine from rough treatment and reduces the cost of repairs. Chapter III. gives directions for setting up a machine. It is rather vague information to be told that the thickness of a belt is "somewhat a matter of taste"; especially when no directions for proportioning the width and thickness according to the diameter of the pulley are given. And it is "putting the cart before the horse" to say that the belt should be half-an-inch less wide than the pulley face. A useful chapter on the coupling of all sorts and conditions of dynamos in parallel and series follows this. The diagrams, which are given in almost every case, are very clear, and the descriptions may easily be followed by inexperienced persons. One regrets that no diagram is given for coupling alternators in parallel, and that this case forms the only exception to the explicit information. If there is any case where a novice is likely to require careful direction, aided by diagrams, it is this case. Only those who "know all about it," as it were, could follow the account given of how to get alternators into step. The directions for testing machines are crowded into a small space and suffer in consequence; but the table of tests may prove useful, and the directions for brake tests are fairly explicit. An appendix, dealing with the "localisation and remedy of troubles," sets out, after the fashion of a "family doctor," the cause, symptom, and remedy for an immense number of dynamo diseases.

Electric Lighting and Power Distribution. Part I. By W. Perren Maycock, M.I.E.E. (London: Whittaker and Co.)

On taking up a small book, provided with flimsy paper covers after the fashion of a cheap catalogue, and looking at its preface, we find that it is designed as an elementary manual for students preparing for certain examinations. Before passing on to review the contents of this work, we may stay to express the opinion that in the hands of an average elementary student this manual would be in fragments before it could steer him to the desired haven of the examination hall. Above all things, elementary text-books require to be well-bound, even though the price must be three-and-sixpence instead of half-a-crown. The reader of this work is expected to have some acquaintance with the fundamental principles of the science of electricity, though a brief recapitulation of the

Hosted by Google

elements is given in the earliest three chapters. Almost the whole of page 14 is filled by a list of "good conductors," the list including such items as "telephonic silicium bronze" and "telegraphic silicium bronze"—a fine distinction indeed; but the list, as it stands, is covered by one word—*metals*. Why should an elementary student be troubled with the doubtful distinction between the terms *conductance* and *conductivity*, or *resistance* and *resistivity*? It will be time enough to use these terms in an elementary class when they are recognised outside a small class of abstract mathematicians whose accurate work demands such niceties, or among scientific pedants. On page 24 there is a technical error, where it is said that in every circuit there is both E.M.F. and P.D. (potential difference). There are important cases where a current is set up in a circuit by the former without the existence of the latter, as, for example, when there is a change of uniform magnetic induction through a closed circular ring. The multiplicity of "screw rules," "clock-face rules," and "hand rules" for finding the direction of a current or of a magnetic field, which we find in Chapters III. and IV., is apt to confuse the beginner, who would do better if given one good rule, or better still if compelled to use his theoretical knowledge alone. Specially confusing to some students is the author's "hand rule" which makes the current flow in the direction of the thumb. A far better known rule makes the current flow in the direction of the fingers of the right hand, while a magnetic needle moves like the thumb. Rules such as these may well be placed in an electrician's pocket-book for ready use by a practical man whose college days are over and whose theoretical notions are getting rusty, but they are likely to be abused if introduced into the college curriculum. Rules like these should never replace theory—which they are prone to do if taught at too early a stage in the course—and the less an elementary student knows of them the more likely is he to seek to master the theory on which they are based. The *pièce de résistance* is evidently Chapter V., which deals with electrical measurement. By far the longest chapter in the book, this covers the ground of electric testing and testing instruments, and deals with the subjects in a manner to be easily understood by a beginner. In one of the many illustrations forming part of this chapter there appears to be a slight mistake. The twisted strip voltmeter shown on page 100 would not work if constructed according to the drawing; for it is essential that the upper half of the strip should be twisted in the *reverse* direction to the lower half. Chapter VI., which concludes this part of the work, deals with the principles and construction of modern dynamos, a subject which is to be continued in Part II. At the end of each chapter a list of questions, to be answered by the student, is to be found; and a few blank pages have been bound in at the end of the book—details which materially enhance the value of the work as a class-room text-book.

Hulfsbuch für die Ausfuhrung elektrischer Messungen. By Dr. Ad. Heydweiler.

This is an excellent reference book for laboratory use, containing, as it does, a description of almost every possible method of making the various electrical measurements necessary in everyday work. A glance at the table of contents will show the completeness of the compilation. Beginning with the usual description of the electrical system of units, the author goes on to describe mirror methods of measurement and treats of period of needles and damping, of suspensions and magnetic control, and measurement of the field at a needle. The second chapter treats of measurement of current, including both constant, intermittent, and momentary flow. Chapter III. deals with resistance, and gives every conceivable method of measurement. Chapter IV. treats of the measurement of pressure and of energy. Chapter V. includes measurement and calculation of the various constants of a circuit or coil, self-induction, &c. Chapter VI. deals with capacity and properties of dielectrics; while Chapter VII. gives methods of determining "v" and the ohm.

A series of excellent tables closes a book of reference which may be confidently recommended to all whose work lies in the direction of accurate electrical measurements. Unfortunately, the book is, as is usual in Germany, very badly bound.

A CURIOUS ACTION OF ATTRACTION BY ALTERNATING CURRENTS.

BY ELIHU THOMSON.

A curious case of apparent attraction of closed circuits in the neighbourhood of an alternating magnetic pole, which was found in experimenting on the repulsive effects, is worth recording.

Let P (*see* Fig. 1) be an alternating magnetic pole, produced by a bundle of iron wires surrounded by a coil through which alternating currents are passed, and C a copper disc considerable smaller than the pole end P. As the disc C is approached to P it will, of course, be found that it is repelled, or that a certain force has to be overcome in bringing it nearer and nearer. It will be found, however, that instead of increasing as nears the pole after a certain position has been

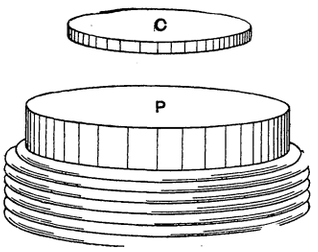

Fig. 1.

passed, the repulsion diminishes, then disappears, and is at last replaced by an attractive force of considerable amount, which increases down to the position of actual contact with the pole. It is assumed that the disc C be kept parallel to, and central with, the pole face P

The explanation of this apparent anomaly is, I think, simple. The attraction appears to be due to the nearness of the disc C to the iron core. Currents are induced in C which, owing to the small diameter, relatively, do not suffer as great lag as when induced in rings or discs which encircle the pole. These currents exert an attraction for the iron of the core which at last becomes superior to the effort of the repulsion, which is feeble. The induced currents in C, in seeking a better magnetic circuit for their induction, cause the disc C to approach the core. The strongest attraction will, of course, exist when the current which energises the pole P is passing its zero value. At this time the attraction will be understood by a glance at Fig. 2, where the magnetic effects of currents in C now have free action on the pole P.

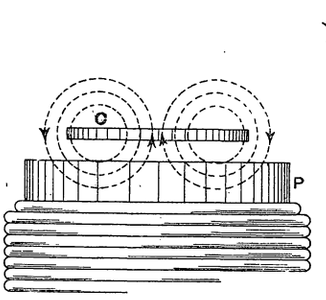

Fig. 2.

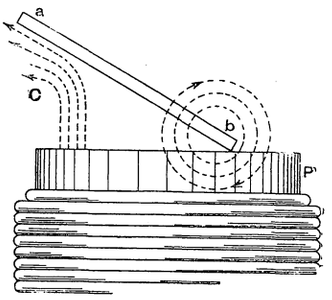

Fig. 3.

A pretty modification of the experiment, and one in which both attraction and repulsion take part, is indicated in Fig. 3. The disc may be set in the position inclined, as shown, and attraction at b may keep it from being thrown off the pole, while repulsion at a sustains something less than one-half the weight of the disc in the inclined position shown. If the alternating pole be presented in a horizontal direction, it will also be found that the disc will adhere to the pole and slip down to a position below the centre. If it slips too far down, the attraction is at once replaced by a quick repulsion which casts the disc away from the pole quite suddenly. With the pole completely inverted or facing outward, the attraction will be sufficient, in some cases, to hold the full weight of the disc against the pole.

A HYSTERESIS THEORY OF BROWN'S ALTERNATING CURRENT MOTOR.

BY J. A. KINGDON.

The single-phase motor of Mr. C. E. L. Brown which is the latest attempt to solve the alternating-current motor problem, has been fully described in *The Electrician* of January 27th, and has no doubt attracted a considerable amount of attention on account of its undoubted novelty and its extreme simplicity. No attempt has been made to explain, or even to indicate, the nature of the actions which produce the motion, but as a clear idea of what takes place in the motor may lead to further developments, it is proposed to investigate the matter in a common-sense fashion, and without recourse to the abstruse mathematical expressions which are so prominent a feature of our *fin de siècle* electricity.

It is usual to commence an attack on alternating-current problems of this nature, with the statement that "secondary currents are in quadrature with the inducing primary currents." The meaning of this expression is, that the induced secondary currents are zero when the primary currents have their maximum values, and are at their maximum values when the primary currents are zero. As the reaction between currents in quadrature is nil, so that no atttaction or repulsion could be set up by them, it is then usual to call in the assistance of *self-induction*, which produces according to this theory a lag of the secondray current and sets up a repulsive action between the primary and secondary currents.

Now, in the first place, secondary currents are *not* in quadrature with the inducing primary currents. Setting aside the initial magnetising current, the behaviour of which has already received consideration in these pages, secondary currents are very nearly cophasal with, but opposite in direction to, primary currents. That is to say, primary and secondary currrents attain the maximum values and zero values at almost identical moments of time. The truth of this statement has been proved experimentally, but it may be pointed out that the mere fact of the "parallel regulation of transformers" proves it conclusively without further experimenting. The reasoning is as follows:—

If the primary of a transformer be connected with a supply of alternating current at a fixed pressure, the pressure at the secondary terminals (allowing for a slight drop at full load) will remain constant for all values of the secondary current from zero to full load. It follows from this that the maximum induction reached in the iron of the core is constant for all loads. But as the secondary current increases from zero to its maximum value, the primary current increases from the initial value of the magnetising current of the transformer on open circuit to 50 or 60 times (in a good transformer) this value at full load. If the secondary current were in quadrature to the primary current, that is, if its value were zero when the primary is at a maximum, the magnetic induction of the core would increase very considerably and the pressures would rise. As a matter of fact, the constancy of pressure shows that the magnetising effect of the induced secondary current is equal and opposite, putting out of the question the initial magnetising current, to the magnetising effect of the primary current. *The secondary current is, therefore, identical in phase and opposite in direction to the primary current.*

Next, as to self-induction. Self-induction is like charity. "Charity covereth the multitude of sins." Self-induction explaineth the multitude of obscure phenomena.

As the writer mistrusts this constant use of self-induction in a vague and inaccurate sense, he will proceed to the investigation of the Brown motor without further reference to it.

The first point that strikes the eye in the diagrams of the various types of motor is that, with one exception, the air-gap between the fixed and moving iron is absolutely uniform, although in the inducing part there are well defined through constantly changing magnet-poles, and not a pair of rotating poles as in the two-phase Tesla-Ferraris motors. If the motor is at rest no movement is set up when the current is switched on, although considerable secondary currents are induced in the windings. If we suppose that a North and South pole are momentarily set up at N and S in the primary magnet of Fig. 1, it follows that the secondary currents tend to magnetise the secondary magnet *n* and *s* with magnetism tending to counteract the magnetism of the primary current, but the latter, having the dominant magnetism, masks that of the secondary current. This is an instantaneous condition of the apparatus when at rest.

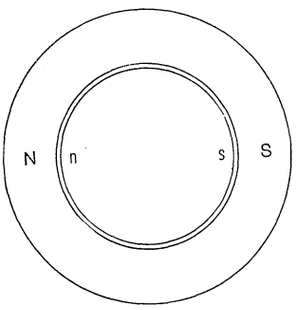

FIG. 1.

If, however, by some device, mechanical or electrical, the motor is once started, the effect of hysteresis comes into play, and different conditions result. The effect of hysteresis or magnetic viscosity is as follows:—A piece of soft iron magnetised by a current retains a good deal of its magnetism even if the magnetising current falls to zero. If instead of reducing the current the magnetic resistance is increased, for example by increasing the air-gap, the same effect takes place. In the Brown

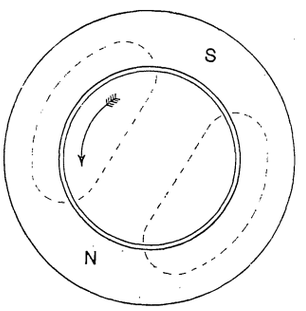

FIG. 2.

Motor the air-gap being uniform, the effects of hysteresis will be particularly marked, the result being that if the interior magnet is moved in the direction of the arrow in Fig. 2, the hysteresis of the iron distorts the magnetic field in the manner indicated in the figure.

Now, the phase of the secondary currents is identical with that of the primary current, but their direction depends upon the position of the resultant magnetic field as distorted by the motion of the inner magnet owing to the hysteresis of the iron.

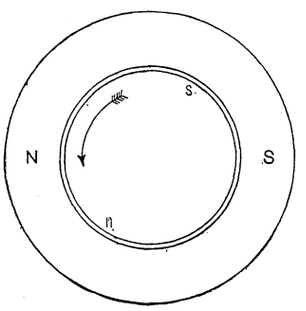

FIG. 3.

The result is, that the polarity set up by the secondary currents is no longer in the line N S of the poles of the primary magnet, but is distorted through an angle as shown at *n* and *s* in Fig. 3.

It will be noticed that the secondary poles in Fig. 1 are of such a sign as to be repelled by the primary poles, but, being in a symmetrical position in relation to them, there is no rotation in either direction, although the rotating part of the motor

Hosted by Google

is in unstable equilibrium. As soon as the polar symmetry of the arrangement is destroyed by the rotating part of the motor receiving motion in one direction or the other, the repulsion between the primary currents and the secondary currents is no longer balanced, but has a resultant in the direction of the arrow in Fig, 3, which is in the same direction as the motion in Fig. 2. It must, however, be remembered that, even if the rotating part of the motor is in motion, the secondary poles would still remain opposite the poles of the primary current, were it not for the effect of hysteresis in distorting the resultant magnetic field of the two parts of the motor. Perhaps it is advisable to point out that the primary current tends to prevent the distortion of the field by the motion of the rotating part, and no doubt does so to a great extent, as long as the value of the primary current is considerable.

The secondary currents, generated as they have been by the previous magnetic wave, and having the polarity of Fig. 3, while they tend to accelerate the motion, also tend to reduce the distortion produced by hysteresis, and, in fact, to distort the field in the opposite direction. Hence there is not much actual distortion of the magnetic field until the primary and secondary currents decrease almost to zero, which, as has already been pointed out, they do nearly simultaneously, and it is near the time of their zero values that the combined hysteresis of the iron and the rotation of the motor produce the distortion of Fig. 2. The effect is, that the next wave of secondary currents are set up with an unsymmetrical polarity, by which, as Mr. Brown points out, "a turning moment is produced."

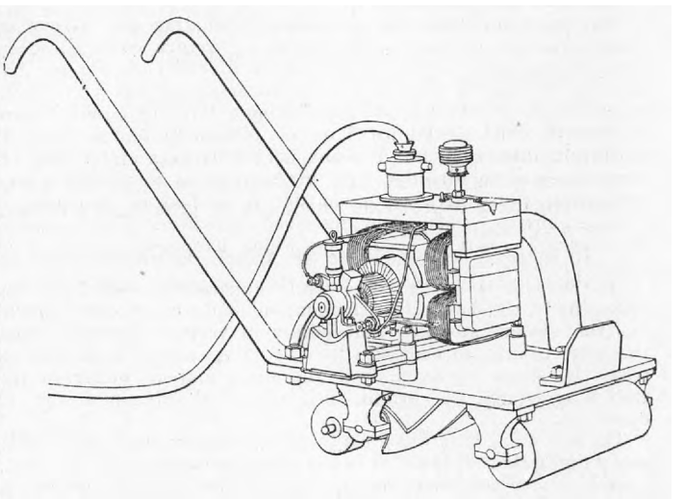
The foregoing explanation may be termed "the hysteresis theory of alternate current repulsions," as distinguished from the "self-induction theory" already alluded to. Experiments are, no doubt, needed to ascertain the exact effect of hysteresis under the conditions of lengthening the magnetic circuit, or rotating part of the iron which composes it, as well as under the conditions of varying the exciting current, and it is hoped that the attention of those who are able to undertake such experiments may be drawn to the matter.

When the cores of the fixed and rotating parts are both smooth and without slots or recesses for the wire, there is no considerable resistance, except that of hysteresis, to the shifting round of the magnetic poles, so that, even if the speed is synchronous, there is no great tendency to keep it so. If, however, the rotating core is deeply slotted, as in Figs. 3 and 4, p. 359, well-defined poles would be set up in the rotating part which would tend strongly to synchronise with the alternations of the current, and every time the poles shifted past a slot the lines of force would cut the thick copper conductors, and set up strong secondary currents which would have a synchronising action.

If the foregoing explanation of Brown's motor is correct, it is likely that hysteresis, which has hitherto been regarded merely as a vexatious and wasteful phenomenon, may turn out to be a property of great value to the electrical engineer.

A NEW ELECTRIC TOOL.

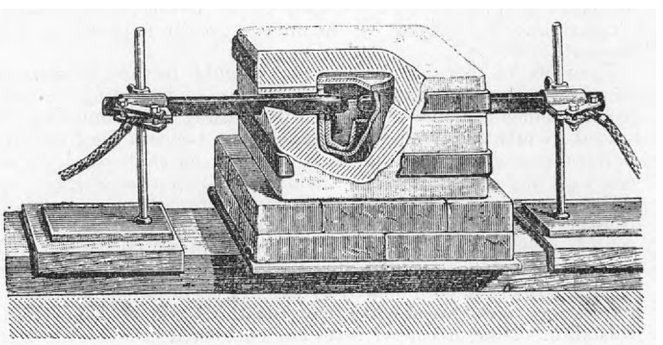
The use of electricity for transmitting power has been steadily increasing during the last few years. Not only is it often found better than mechanical transmission, but in many cases it enables mechanical power to be applied to work where, without electricity, it would be quite impracticable to use anything but hand power. One of the latest machines of the latter kind, our illustration shows, is an electric deck-planer, invented and patented by Mr. Malcolm Sutherland, electrical engineer to Messrs. Wm. Denny and Brothers, the well-known shipbuilders of Dumbarton. It is used for planing the decks of the ships, and is so simple in construction that very little explanation is necessary. The tool resembles a lawn mower in form, and is handled in the same way, and with as much ease. A steel base plate is mounted on rollers, and on the underside of this the revolving cutter is fixed. The electric motor is geared to the cutter by means of toothed wheels. One of Rawlin's spiral cutters is used, and revolves at a speed of 3,000 revolutions per minute, the motor having a speed of 2,000 per minute. The rollers which follow are fitted with eccentric journals, so that by moving a lever they can be raised or lowered and the depth of cut nicely adjusted. The machine does very good work, is faster than hand planing, and relieves the men of a very dis-



agreeable job, as the planing of decks by hand involves kneeling, or sitting in a very uncomfortable position. Current is supplied to the motor by means of a twin flexible lead, and the whole machine is of a very compact and portable nature.

THE MOISSAN-VIOLLE ELECTRIC FURNACE.

At a recent meeting of the Académie des Sciences MM. Moissan and Violle exhibited one of their electric furnaces made by M. Nion, head of the Physical Laboratory Workshop at the École Normale. The essential feature of the furnace is a closed cylindrical carbon vessel, having a diameter equal to its height, the material being an agglomerate of tar and powdered retort carbon. This vessel consists of a carbon tube resting on a slab of carbon, and having another slab of carbon resting on it at the top. Inside this cylinder a carbon crucible is placed, as shown in the figure. The whole is enclosed in a block



of limestone, similar to those employed by Deville and Debray, in their platinum-melting experiments. The carbon vessel does not touch the walls of the limestone block, but is separated from it by a 5mm. air-gap, the bottom resting on magnesia supports. The dimensions of these furnaces depend, of course, on the purpose for which they are intended. When currents of between 300 and 500 amperes are to be used, MM. Moissan and Violle employ a carbon cylinder 6·5cm. in diameter, carbon electrodes 3 to 3·5cm. in diameter, and a block of limestone 20cm. high, 2·5cm. broad and 30cm. long, the lid having a thickness of 4 to 5 cm. The carbons are held in iron sockets carried on movable uprights.

GROUND PLATES VERSUS A CONTINUOUS COPPER RETURN.*

A very unusual and singular occurrence took place on an extensive electric railway system in the north-west last month, during a spell of unusually cold weather, which has attracted considerable attention in the electrical field.

The question of the proper method of bonding the rails of an electric railway, or otherwise providing a "return circuit," seems from current practice to admit of a great diversity of opinion; but latterly this part of electric railway construction has been given more attention, with a view to providing a "return circuit" more consistent with the known laws of electricity and economical operation of the system. The unusual occurrences on the road referred to bear so directly upon this subject as to present a very favourable illustrative argument for a method of providing a "return circuit," such as is described hereafter. The essential features of the various occurrences which happened on this road were as follows:—

In the middle of the day, while apparently everything was operating to the best of satisfaction, suddenly every car throughout the system stopped, and horses in various localities about the city, coming in contact with the rails, were knocked down from the shock received, and the main ampere meter in the station registered no current, although all the dynamos were in operation.

The first thing that was done to try to remedy the trouble after ascertaining that all fuses, switches, dynamo connections, &c., &c., were in proper condition, was to run from the negative line bar in the station a cable into an adjacent river bed, thus providing an excellent ground for the dynamos. But this did not obviate the difficulty; the ampere meters still registered no current, and cars refused to move; this proved conclusively that it was not lack of dynamo grounds that caused the trouble. Attention was next directed to the track feeders, which were buried in the ground and connected the track with the negative sides of the dynamos. They, upon inspection, were found with their soldered connections melted, the wire itself very hot and burned for a length of two feet. A new cable was immediately provided in place of the burned one, and the road then started up in as good order as before.

That the earth was in a condition offering great resistance to the flow of electricity through its surface, either on account of its being in a dry frozen condition or for some other peculiar local condition, or that the rails themselves were practically insulated from the earth, which, when it is considered that ice is a very good insulator, it can easily be imagined possible to occur in cold weather, is very evident from the fact that the soldered connections in the track feeders were melted. This melting of the connections would only have occurred by reason of excessive current passing through them, which being the fact, occurred because the rails alone were conducting approximately the entire amount of current necessary to operate the system back to the station. This could only occur when the earth was in a condition offering great resistance, as compared with the rails, or when the rails wore insulated from the earth, for usually under normal conditions the "return circuit" offered by the rails is greatly supplemented by the earth itself.

The facts of this case being thus brought to view, present in themselves a strong argument in favour of providing suitable grounds along the line of an electric railway, by connecting the rails at frequent intervals to the moist earth beneath the frost line. Besides preventing such mishaps occuring as shutting down an entire railway system, it would furthermore prove a valuable adjunct in the economical operation of a railway, for it would very materially decrease the total resistance of the circuit. In this manner dry earth is a very poor conductor. The earth in actual contact with the rails is dry during the greater part of the year, particularly in summer; thus the path offered by the dry earth for the current to find its way to the moist earth underneath is one of considerable resistance. Now, if copper wires are connected between the rails and the moist earth an easy path of very little resistance is immediately provided, and as it is desirable to have as much current return through the moist earth as possible, as being a medium offering the least resistance, infinitely less than the rails, the advantages of this method of construction are very apparent. These grounds should be provided at least every tenth of a mile, or as much oftener as circumstances will admit. The wire should be as large as No. 0 B. and S., and connected to both rails if a single track, and to all four rails if a double track road.

If without these track grounds there is any advantage in running a copper return wire the whole length of a railway, a method of construction the economy of which is very much to be doubted, with these track grounds it is only a useless expense, for in providing a conductor of no resistance for "the return," as is a case in using the moist earth, why supplement this by another one of infinitely greater resistance, as would be the case in a copper return wire? Another difficulty overcome by providing these track grounds is the complaints made by telephone companies, where they themselves use the ground as a return, that at a certain period adjacent electric railways cause all their annuciators to drop in the central office. This is due to the railway not having efficient track grounds, in which case the current seeking to "return" through the dry surface of the earth, runs across a grounded telephone wire. This offering a path of less resistance than the dry earth, it immediately chooses this wire upon which to return. Thus, passing through the telephone central office, it drops all their annunciators. This fault can be obviated by providing efficient track grounds in manner as above described.

* From the *Street Railway Review* of Chicag›

INDIRECT LIGHTING.*

Our Viennese contemporary, *Der Gastechniker*, in its issues, Vol. XVIII., Nos. 6, 7, 8 and 9, gives a series of Papers by Dr. Franz Menning, which originally appeared in *Der Gesundheits-Ingenieur* (the *Sanitary Engineer*), on the subject of indirect lighting. The Papers are based on experiments made by Dr. Menning in the Hygienic Institute of the University of Halle. He remarks that short-sightedness in school children is often due to insufficient lighting, which makes them bring their eyes too close to their work, and thus makes them squint, and damages the accommodation of the eye. In many instances this is the case even with daylight, as, for example, in buildings in narrow streets and so on; but artificial light is usually in a still worse case. It is only recently that we have been able, since the introduction of Weber's photometer, to measure the actual illumination in such circumstances. Another serious cause of injury to the eyes is the fact that in many schoolrooms, lecture-rooms, and the like, there are many lamps or burners used, and that these, or some of them, are in sight, and worry the eye. The lamps are also often overhead, and cast a strong shadow of the writing hand, or of the head, or of the upper part of the body; and this strains the eye. Farther, the distribution of the illumination tends to be very unequal; in a lecture-room in the University, the illumination of the six seats on one bench was found to be 8·4, 12·7, 45·8, 74·9, 16·9, and 11·0 candle-metres;† the reason for this extreme inequality being that an argand lamp was suspended above the middle of the bench, and fitted with a polished reflector. Another evil is, that reflectors send down radiant heat; and this makes it necessary to put the lamps higher up, with the result that less benefit is derived from them as illuminants. Daylight does not present these disadvantages, at any rate to a corresponding degree, and it appears desirable to assimilate our artificial lighting to daylight, so far as may be.

Daylight is diffused light; lamplight is direct light. The problem accordingly is to transform direct light into diffused light. In order to accomplish this, the device has been hit upon of placing white reflectors under the flame, and throwing the whole light upwards on the ceiling, the flames themselves not being then visible. This seems to have been first done with arc-lamps, in the Paris Electrical Exhibition of 1881, and in the Vienna Anatomical School, and also the Industrial Museum. It was also done in two engineering drawing-rooms in Leipzig; metallic reflectors, white varnished internally, were used under bare arc lamps; the ceiling was the brightest part of the room, and the lower part looked as if it were dark, but for working purposes was found not to be so, even for fine drawing work. Prof. Erismann, of Moscow, first introduced this method of illumination into schoolrooms in 1888. The lamps used were petroleum lamps. He illustrated the method in the Moscow Exhibition of that year. The visitors were unanimous in their approval; there was nowhere any trace of shadow; it was equally easy to read at all points in the room, and also easy to do all sewing, except stitching in black. The contrast between the shadows under the hand by direct lighting and their absence under the new method was very striking. There are, however, no data as to what was the loss of lighting power as compared with the older method; and it seemed desirable to ascertain this.

Through Prof. Renk's favour, Dr. Menning has had the opportunity of doing this in the University of Halle. The lecture-hall of the Hygienic Institute is fitted up with four Butzke regenerative lamps, placed so near the ceiling that their products of combustion escape at once through openings in it. The flames themselves are about 9ft. 4in. above the desks. Above the lamps are milk-glass reflectors. The four lamps form a rectangle of 11 square metres area, while the area of the floor is 28 square metres. The illumination had been previously ascertained to be over 10 candle-metres on the average, and was therefore considered sufficient. These lamps are now fitted, for the new method, with

* From th *G World.*

† 1 cand.e-metre = approx. one tenth of a candle foot (·089).

Hosted by Google

removable mirrors below them, and the downward reflectors temporarily removed. The mirrors placed below entirely hide the flames, and they are segments of spheres, with a diameter of 24in., and corresponding to an angle of 120deg. ; they are painted white inside and then varnished. The effect seems to astound all who come in. The hall seems divided into two zones, the upper bright and the lower dark ; but both reading and writing are found to be easy when a seat is taken at any one of the desks. There is no shadow, no reflection from the walls ; the flames are out of sight, and the lighting does not cause radiant heat to strike upon the head. The subjective impression is pleasant, as the members of the German Association of Science found during their Halle meeting ; the only defect is the comparative darkness of the lower part of the room. But these are not measurements ; and actual measurement brought out less satisfactory results. Using a Weber photometer at the desk-level and at the demonstration table, it was soon found that it was not necessary to take measuremements at every point, and that it was enough to do so at the corners and the middle of the hall. The main result was that with the same consumption of gas, the illumination in the brightest place was 26·15 candle-metres with direct and 8·59 with indirect lighting ; that in the darkest it was 16·58 and 6·74 respectively ; and that the average values were 21·33 and 7·64 respectively. Now this shows that the average is seriously reduced ; there is an average loss of no less than 64·2 per cent. ; and in order to maintain the former standard of brightness three times as much lighting power would have to be employed. Besides, the light was not really sufficient ; no illumination less than 10-candle-metres* is so. On the other hand, the absence of shadow, the great uniformity of the illumination, the absence of wall-glare, and the invisibility of the flames, seemed to offer encouragement to go forward, and try to overcome the defect of the indirect method.

The next thing then was, since the walls of the room were dark in their lower portions, to paint everything pure white. The effect was that in the brightest place the illumination was 33·29 candle-metres by direct, and 10·20 by indirect lighting ; in the darkest 18·20 and 8·43 respectively ; and, on the average, 24·01 and 9·11. The illumination by both methods had thus been improved ; but the indirect showed a loss of 62·5 per cent. It was now found that the glass lids of the lamps were not air-tight. This was put right. The averages then were 27·05 for the direct, and 10·76 for the indirect lighting ; but still the indirect showed a loss of 60·2 per cent. ; but there was now enough light in the lower part of the hall.

The next idea was to use some semi-transparent material for the reflectors. Paper was accordingly used in the first place. The results then were, brightest place 25·29 and 10·84, darkest place 16·44 and 8·43 ; averages 21·01 and 9·94 ; loss 52·7 per cent. These results are less favourable than in the previous experiments, because these tests had to be made by day, and the gas pressure was not good ; but the loss had been, in proportion, substantially reduced. Paper is, however, not a good material ; it becomes brown and useless.

The next material tried was milk-glass ; the object was to find a kind at once as transparent and as good a reflector as possible. These two qualities are, of course, mutually inconsistent ; so a medium quality of glass had to be employed. This was used in slips fitted radially in a frame ; the upper edge of each slip was rounded off, so that there was no distinct shadow on the wall dividing the room into two zones. The impression produced was more pleasing ; the room looked much brighter, and yet there was nothing blinding. The illuminations were, brightest place 32·04 direct, 11·79 metallic reflector, 13·79 paper, and 19·28 milk-glass reflector ; darkest place, 21·75, 9·08, 10·62, and 13·50 respectively ; averages, 27·05, 10·76, 12·82, and 17·48. This shows how greatly the average illumination is increased by the use of the semi-transparent reflectors ; and that the loss on the average is by their means reduced to 35·6 per cent. The worst-lit part of the room is more than sufficiently lit ; and the loss of 35·6 per cent. can be borne, especially when we already often lose 60 per cent. through the use of opal globes, and the like. On the other hand, the lighting is distinctly not so uniform with the semi-transparent reflectors as it is with the opal ones. The semi-transparent reflectors are something intermediate between direct lighting and indirect lighting pure and simple, and it is therefore a compromise ; the light is not quite uniform, and shadows are not entirely absent ; but it is a very great improvement on direct lighting. It is a question of circumstances whether one will adopt the one extreme or the other in special cases ; if the lighting power is limited it may be necessary, in order to have enough light at all, to hold by direct lighting. On the other hand, if a loss of two-thirds of the light can be afforded, as in the case of arc lighting, metallic reflectors might be used. For many purposes, however, the new middle way is the best ; and, besides, it is a method which, on account of its coolness, enables the lamps to be hung lower down, to the better utilisation of their direct lighting power.

* Roughly one candle-foot.

LEGAL INTELLIGENCE.

Henley's Telegraph Works Company v. Scott.

In the Queen's Bench Division, on Monday and Tuesday, this case came before Mr. Justice Smith.

The action was brought to recover the price of four submarine cables supplied to defendant's order, and the defence was that the cables were not made as ordered, a counter-claim being put in for the extra cost of cables which defendant had to purchase in consequence of the rejection of those supplied by the plaintiffs. From the evidence it appeared that the defendant, Mr. Ronald Scott, tendered to the India Office for the carrying-out of certain electrical work ; amongst other things required were four different classes of cable, which he did not himself manufacture. He obtained an estimate from the plaintiffs, incorporated with his tender prices for the cables, and obtained the contract. Mr. Russell, at that time manager for Mr. Scott, and Mr. Potter, traveller to the plaintiffs, attended at the Admiralty Office for the purpose of inspecting the patterns there shown.

For the plaintiffs it was contended that it was upon these patterns that their tender was made out, and the order given to them, it being asserted on their behalf that no specification was shown to Mr. Potter.

Mr. RUSSELL stated that he did show the specification to Mr. Potter, gave him extracts from it relating to the work, and gave him distinctly to understand that the work was to be done according to specification, and not according to patterns.

Mr. MORRIS, custodian of the Naval store patterns at the Admiralty Office, said it was part of his duty to explain that the patterns were intended only to show the class of work required, but that the work itself must be carried out in exact accordance with the specification.

PLAINTIFFS further alleged that they sent samples of the cables they intended to supply, and that no objection was raised to them. The cables required were of different classes, and some, which had to be lead covered, they were obliged to get done by the Fowler-Waring Company.

DEFENDANT denied having received any samples of lead-covered or jute-insulated cable such as plaintiffs asserted they had forward to him ; the only samples he received were insulated with vulcanised india-rubber, and these he sent to the India Office with his estimate. When the cables were sent in some of them, insulated with jute, were rejected. The India Office pressed defendant to complete his contract, and he had to purchase the cables elsewhere at a price in excess of that at which plaintiffs had contracted to supply them. This formed the subject of his counter-claim.

Mr. REED, Q.C., on the part of the defendant, and Mr. DURAND, on behalf of the plaintiff, having addressed the Court,

His LORDSHIP gave judgment on Tuesday morning. He said he had not for many years come across a case of a mercantile character where there was such a direct conflict of evidence ; he did not think any of the witnesses called had wilfully told him what they knew to be untrue, but that one side had made a blunder there could not be the slightest doubt. The action was for the price of work done under contract, and the defence was that it was not done according to contract. It so happened that there were two Admiralty specifications for submarine cables, one dated April 16, 1890, and the other June 17, 1891, and the difference between them was that, whereas under the first the Admiralty would take cables insulated with jute, under the later specification they required the insulation to be of india-rubber. The cables claimed for were made under the earlier specification. The first question which was in dispute in the case was as to what took place at the interview between Mr. Russell and Mr. Potter, at the Admiralty pattern office on September 16, 1891. Mr. Potter's evidence was that he saw a pattern and that Mr. Russell had no document with him at all excepting one in writing ; it was upon the pattern that he contracted and that the cables were made. The question was, was Mr. Potter's memory accurate and clear. In his opinion it was not. He had himself admitted that he might have said that the patterns must have been there for ages. But his recollection was indistinct as to how be became possessed of the document containing figures taken from the specification, and as to what was said about the specification itself. Mr. Russell's evidence was clear and positive. He said he had the specification with him, and took it out and went through it for the purpose of showing Mr. Potter what it was that was wanted ; indeed, he could not have obtained admission to the Pattern Office unless he produced the specification, and confirmatory evidence upon this point was given by Mr. Morris, who had no interest in the case at all. It, therefore, seemed to him that the plaintiffs had not made out that the order was given on the jute pattern, and not on the specification. His lordship further held that there was no evidence that samples of the lead-covered cables had ever been sent to the defendant. His view was, that the defendant and his witnesses were right, and that the plaintiffs had not proved that the contract was to make cables according to the patterns. That being so, the plaintiffs' case failed, and they were not entitled to the price of the cables, but the defendant was entitled to the amount of his counter-claim, the amount due to defendant, therefore, being £44. 2s. 11d.

Suren, Hartman and Co. v. Henley's Telegraph Works Company (Limited).

In the Chancery Division, on Thursday last week, Mr. Justice Stirling gave judgment in this action, which was brought for repayment of £500 paid by the plaintiffs in respect of certain shares taken by them in the International Cable Company (Limited). His Lordship declared that "the defendant Company are bound to repay to the plaintiffs, either in cash or in fully paid up shares of the International Cable Company (Limited), at

Hosted by Google

the option of the defendant Company, the sums of £250 and £250 paid by the plaintiffs upon application for and allotment of the shares." Costs were also granted against the defendants, to whom two months' time was allowed to repay the £500 either in cash or shares.

Woodhouse and Rawson v. Judd, Lindsay, and Co.

This case was struck out of the list on Wednesday morning, nobody appearing upon either side.

AMERICAN NOTES.

(FROM OUR OWN CORRESPONDENT.)

NEW YORK, *Feb.* 25, 1893.

The Goebel Lamp.—Since my last letter the suit by the General Electric Company against the Beacon Vacuum Pump and Electric Company of Boston, for an injunction to restrain from the sale of the lamp infringing the Edison patents, has been decided by Judge Colt in favour of the General Electric Company, the basis of this decision being that while the Goebel lamps 1, 2 and 3, which were offered by the defence in evidence of an anticipation of all that is essential in the Edison patents, were not practicable commercial lamps, and that while No 4, another exhibit, probably was a practical lamp, in the opinion of the Judge the date of its manufacture was involved in great doubt, it not having been proved to his satisfaction that it existed before the issue of the Edison patent; in fact, in the Court's opinion, the presentation and claims for this lamp involved the whole defence in a cloud of suspicion, and for this reason judgment was given for the plaintiff. While this was merely a preliminary trial, and the injunction was merely temporary, it was regarded as of the utmost importance as indicating how such a defence at this late day would be regarded by the higher courts. While the defendants are disappointed they are evidently not discouraged, and it is expected that a more vigorous defence on the same lines will be made when the case against the Columbia Company comes up for final hearing in St. Louis next month. The latter case is exactly similar to the Beacon case, the Columbia Company having been enjoined some time ago.

NEW YORK, *March 10*, 1893.

The St. Louis Meeting of the National Electric Light Association.—The National Electric Light Association held its sixteenth convention in St. Louis. The attendance was exceedingly large and representative of the electric-lighting interests of all parts of the country, and the interest was maintained undiminished to the end. The Papers read were of a higher grade than those usual at these conventions, and were largely of a practical nature as was fitting to the occasion, which, it will be remembered, was a convention of purely business men engaged in the electric-lighting interests. The titles of the Papers read, and their authors, are as follows:—"Wrought v. Cast Iron for Field Magnet Frames," by A. D. Adams; "The Relation of Insurance to Electric Lighting and Power," by Capt. Wm. Brophy; "Some Experiences with the Alternating System," by R. H. Sterling; "Thermal Storage for Central Stations," by Prof. George Forbes; "Long Distance Transmission of Powers," by Chas. S. Bradley; "Power Transmission for Central Stations," by Dr. Louis Bell; "Remarks concerning Power Transmission from the Economic Standpoint," by L. B. Stillwell; "The Vulcanising Process for Preserving and Strengthening Poles, Cross-arms, Ties, etc." by Harry C. Myers; "Underground Conduits and Conductors and the Experiences of Electric Lighting Companies of New York City," by Wm. H. Browne; "The Incandescent Lamp from a Commercial Standpoint," by Calvert Townley; and "Morals of Corporations," by E. A. Armstrong. In addition to the Papers read, a lecture was given by Mr. Nikola Tesla, on Wednesday evening, in the immense auditorium and grand music hall of the Exposition Building which was packed to its utmost capacity by those who were anxious to see and hear this already famous experimenter. Prof. George Forbes who has but recently arrived in this country, read a Paper on "Thermal Storage," a subject which has excited so much interest in England. His remarks were, therefore, listened to with great attention, and gave rise to an extended discussion which brought out many additional points of interest, which constituted one of the most important of the Papers before the convention. The attitude of the General Electric Company towards the outside electrical interests of this country during the past few months has so antagonised those interests that it seemed probable that the matter would become the topic of chief interest at the convention, and there were those who looked forward to its assuming such an aggravated phase as to endanger, if not disrupt, the Association. As a matter of fact, strong feeling was manifested on both sides, and it was only through fine generalship of the managers that it was kept within bounds. Although the subject was not one announced for discussion, Mr. Townley's Paper on the "Incandescent Lamp from a Commercial Standpoint" was made a pretext for this discussion. The matter was happily terminated for the present, however, without serious rupture between the two factions by reference to a Committee. At the election of officers for the ensuing year, two candidates became prominent for the Presidency, one of whom was supposed to be friendly to the General Electric Company's interests, and the other to be representative of the outside interests. Before the matter came to a vote, however, the General Electric Company, finding itself overwhelmingly outnumbered, made no fight, and the following were elected:—President, E. A. Armstrong; First Vice-President, M. J. Francisco; Second Vice-President, C. H. Wilmerding; Secretary, Geo. F. Porter. The place for holding the next meeting was referred to the Executive Committee. In reviewing the electrical situation in this country there is more, by far, than appears on the surface. The General Electric Company, although presumably acting within the law, has so aroused public opinion against it as to seriously embarrass it. In its recent intended fight at the St. Louis convention, it was defeated at every point, as it found united against it all other interests, as if against a common enemy, and it would seem as though it must realise that it has made a mistake in antagonising in this manner the public interests, and it is hoped that this will result in an adoption on its part of a more generous policy than that it has heretofore pursued.

TRADE NOTES AND NOTICES.

[*Notices for insertion under the above heading must reach the Office not later than first post Thursday morning. New Catalogues, Price Lists, and similar matter should be sent early in the week.*]

The 1893 Edition of "THE ELECTRICIAN" Electrical Trades' Directory and Handbook is NOW READY. This useful book contains over 1,000 pages, and several new and handy features have been added. Price 7s. 6d., post free 8s. 3d.; abroad 8s. 10d. Comparison with any similar electrical publication is specially invited.

TENDERS INVITED.—The Directors of the Lancashire and Yorkshire Railway invite tenders for the supply of a variety of articles for the twelve moths ended April 30, 1894. Some particulars are given in our advertising columns, and further information and forms of tender can be obtained at the Stores Department, Osborn-street, Manchester, where samples of the articles required can also be examined. Tenders must be lodged with Mr. C. W. Bayley, secretary of the Company, not later than 10 a.m. on Monday, April 3rd.

——— Our advertisement columns contain a notification that the Corporation of Brighton invite tenders for the supply and erection of electric arc lamps, switches, and lamp canopies. Tenders must be left at the office of the Town Clerk before 10 a.m. on Tuesday, the 4th prox.

——— Tenders are invited for the stock, plant, machinery and effects of a going concern in the electrical and general engineering trade, together with its patents, licenses, goodwill, trade name, &c. Some particulars appear in our advertisement columns, and all information can be obtained from Messrs. Lakeman and Oliver, Prudential-buildings, Park-row, Leeds, to whom tenders must be sent not later than the 12th prox.

——— The French Post and Telegraph Department invites tenders for the supply of 825,000 porcelain insulators (in five lots). Information as to the schedule of prices can be obtained from the Division du Matériel et de l'Exploitation Électrique (3me bureau), 103, Rue de Grenelle, Paris, where tenders will be opened at 11 a.m. on Thursday next, the 30th inst.

Hosted by Google

TENDERS ACCEPTED.—We learn that the tender of Messrs. Alexander Brown and Sons has been accepted for the boilers, fuel economisers, engines, condensers, travelling crane, feed-pumps, steam-pipes, &c., required in connection with the scheme for lighting Derry City by electricity, the amount being £4,293. The tender of Messrs. Siemens, Bros. and Co. has been accepted for the dynamos, regulators, switchboard, arc lamps (Brockie-Pell), lamp carriers, and underground conductors, the amount being £8,905.

——— The tender of Messrs. Edmundsons (Limited) has been accepted for the electric lighting of the new asylum buildings at Ryhope by the local authorities, the amount of the tender being £4,083.

THE "BELGIAN" LAMP.—We have received a copy of the price-list issued by the Belgian Lamp Manufacturing Company, of Antwerp, containing particulars of the Company's incandescent lamps, and useful formulæ relating to lamps and carbons.

MESSRS. HURRY AND YOUNG.—Under this title a new firm of electrical engineers and contractors has taken premises at 16, Princes-street, Edinburgh.

RE F. SILVESTER AND CO.—The first meeting of creditors in this matter was held on March 15th, in which the adjudication under the trusteeship of Mr. C. E. Buller, C.A., Albion-st., Hanley, Staffs., with a Committee of Inspection, was decided upon, the Trustee being authorised, with the consent of the Committee of Inspection, to carry on the business for a period not exceeding six months, with a view to disposing of same as a going concern.

DEED OF INSPECTORSHIP.—A deed of inspectorship has been signed by Arthur Adam Mather and Edward James Mather, trading as gas and electrical engineers at 278, Caledonian-road, and 12, Charles-street, Hatton-garden, with a view to the payment of a composition of 12s. in the £1. The total debts are £681. 17s. 8d., and the net assets £408. 12s. Mr. R. J. Ward, Bloomsbury-mansion, Hart-street, Bloomsbury, is the trustee.

IN BANKRUPTCY.—The first meeting of the creditors of A. H. W. Radcliffe is to take place at 23, Colmore-row, Birmingham, on April 6th, at 11, and the bankrupt's public examination will be held at the County Court, Birmingham, on April 19th, at 2.

PARTNERSHIP.—Messrs. Marchant and Co., of Clerkenwell-road, electric light contractors, announce that they have taken into partnership Mr. C. Townend Young, of Sheffield, and that the firm will for the future trade as Marchant, Young and Co.

PERSONAL.—Mr. E. Mann, secretary of the Woking Electric Light Company, has accepted a similar appointment at Kingston-on-Thames.

BIDEFORD.—A Local Government Board inquiry has been held here on the question of the application by the Town Council for a Provisional Order to empower them to purchase the Gas Works. Considerable opposition to the scheme was shown, many of the largest ratepayers objecting to the purchase. Several of the opponents of the scheme stating that they have under consideration the introduction of the electric light to their private and business premises, Mr. H. P. Tabdrew announced that he had prepared a competitive scheme for lighting the district by electricity with an outlay for plant of £4,600, and an annual expenditure of £620.

BOLTON.—The Electric Lighting Sub-Committee have made the appointment of electrical engineer for the Borough. Sixty-two applications were made for the post, which were subsequently reduced to eight, and included Messrs. A. S. Bernard, H. J. Crews, W. H. Heyes, J. Oddy, J. B. Mitchell, J. Sheppard, J. H. Rider, and C. H. Yeaman. Ultimately Mr. J. H. Rider, of Halifax, was selected. This gentleman has previously held two important electrical engineering appointments, and his new position carries a commencing salary of £200 per annum. It will be remembered that the Corporation of Bolton have recently applied for powers to borrow £40,000 for electric lighting and power transmission purposes.

BOWNESS.—At a meeting of the Police Commissioners, Mr. Law recommended the purchase of ground on the banks of the Avon for electric-lighting station purposes, and stated that there was sufficient force of water in the Avon to provide power for lighting the whole of the Bowness district. The matter is to be further discussed at the next meeting.

CARLISLE.—The Town Council have agreed to an expenditure of £1,600 for the electric lighting of Tullie House. The plant includes duplicate engines and dynamos. The Mayor, in supporting the vote for the expenditure, pointed out the superiority of the electric light over gas in an institution like Tullie House, where books and pictures are kept.

EDINBURGH.—A report has been received from Mr. David Cook, mananger and engineer of the City of London Electric Lighting Company (Limited), acting as additional adviser to the Committee who have this matter under consideration. Mr. Cook expresses complete agreement with Prof. Kennedy's report, and remarks that no town which has the working of the electric light in its own hands has been compelled to draw upon the rates. He also calls attention to the saving to be effected on the expiry of the lamp patents.

THE ELECTRO-HARMONIC SOCIETY.—A smoking concert will be held in the banquet room of the St. James's Hall Restaurant, Regent-street, W., on Friday, April 7th, at eight o'clock.

FALMOUTH.—The Urban Sanitary Authority have had under consideration the question of lighting the town by electricity. Several schemes have been recommended for acceptance; but in the report of the Lighting Committee, discussed at the last meeting, a suggestion received support that a Provisional Order be obtained and the necessary capital borrowed by the Town Council, the Order to be then transferred to a Company (the latter paying the Town Council 5 per cent. on the capital expenditure, and also providing an annual sinking fund) provided satisfactory guarantees were first secured. Further consideration of the subject was postponed.

HANLEY, STAFFS.—Some misapprehension has arisen from a note appearing in our issue of March 10th announcing that tenders were required by the County Borough of Hanley for the contracts in connection with their electricity works. The note should have read for "the building contracts." Tenders have been duly received by the General Purposes Committee of the Town Council for this building work, and a contract has been entered into with Mr. C. Cornes, of Hanley, for the erection of buildings and chimney shaft for the sum of £2,990. The borough surveyor has been instructed to report upon the details of the street lighting by electricity within or adjacent to the compulsory area. In September last the tender of the Brush Company was accepted for the electrical and engineering plant for the amount of £15,760, and the sanction of the Local Government Board to the borrowing of £21,000 for the electric lighting work has been duly obtained.

HUDDERSFIELD.—The County Borough Council at their last meeting empowered the Mayor, Chairman, and Vice-Chairman of the Electric Lighting Committee to proceed to Sheffield to inspect a system of electric mains which has been adopted there, with a view to a similar plan being adopted at Huddersfield.

ILFORD.—As a result of the Lighting Committee's investigations, and on consideration of the report of the expert appointed by the Local Board, the Lighting Committee at their last meeting announced that they were unable to recommend a scheme of electric lighting.

ISLE OF MAN.—An application will be made early in April by the Douglas and Laxey Coast Electric Tramway Company (Limited) for power to construct an electric tramway through the parish of Lonan and the village of Laxey, and for the compulsory purchase of the necessary lands for the purpose.

LECTURES.—Lectures have lately been delivered on electrical subjects by Mr. S. Vyle at Derby, Mr. Mundella at Wolsingham, Dr. Dawson Turner at Edinburgh, and Dr. Riley at Dewsbury.

LLANDUDNO.—The Improvement Commissioners at their last monthly meeting discussed the question of sanctioning the erection of an electric tramway, provided the route and other detail arrangements were approved by that body. In the result the motion for sanction being given was lost. Mr. E. P. Stephenson, C.E., Engineer to the Commissioners, presented his report dealing with the electric lighting of the town, in which he estimated the first cost of the installation, including lands and buildings, at £15,000, and the annual cost of maintenence at £1,435. He further estimated that, in order to meet the necessary charges, electrical energy would have to be produced at 5d. and sold at 9d. per unit. The report is to be circulated and considered at the next meeting.

MONTROSE.—At the next meeting of the Police Commissioners a resolution will be moved that a committee be appointed to consider the advisability of lighting the town by electricity with a water-power generating plant.

MOSS SIDE (MANCHESTER)—At the last meeting of the Local Board the Chairman announced that he had been making inquiries with regard to the practicability of lighting the district by the electric light, and he hoped the Board would not rest satisfied until they had brought about this desirable improvement.

NEW DECIMAL ASSOCIATION.—At a meeting of this Association, recently held, it was decided to concentrate the efforts of the Association to the adoption of the decimal system to weights and measures, leaving the coinage to be dealt with subsequently.

NEWMARKET.—Mr. E. C. de Segundo has sent in his report on the electric lighting of Newmarket to the holders of the Provisional Order. He estimates the cost of the necessary works for the

Hosted by Google

immediate requirements at £13,000, and recommends the adoption of a low-tension system.

NORTH KENSINGTON, LONDON, S.W.—A discussion upon the subject of electric lighting for the northern district of the parish is to occupy the next meeting of the Ratepayers' Association.

OMNIBUS LIGHTING.—Many Sheffield omnibuses are being lit by the electric light, the apparatus including a small switch under the control of the 'bus conductor.

PEMBROKE.—The Admiralty contemplate introducing the electric light at the Pembroke Dockyard.

RICHMOND (SURREY).—At the last Town Council meeting the report of the Electric Lighting Committee was discussed, and Messrs. Latimer Clark, Muirhead and Co.'s observations on certain objections made by Mr. Shoolbred as to the mains proposed to be laid by that Company were finally disposed of. It was recommended that the Council consent to the Company's mains being laid in accordance with their arrangement. Councillor Thompson stated that upon every objection made by Mr. Shoolbred the Council had supported the contracting Company, while Councillor Pillans stated that Mr. Shoolbred was now diametrically opposed to the recommendation he had himself first proposed, and had (said Mr. Pillans) turned an "intellectual somersault." It appeared to him (Mr. Pillans) that they paid their engineer £50 a year for altering his opinions. The Committee's recommendations were adopted.

SILKSWORTH.—The extensive Co-operative Stores have recently adopted the electric light, and the Seaham Harbour Co-operative Society, and several other similar societies in the County of Durham, are following suit.

SOUTH AFRICA.—A telephone line has been laid between Leydsdorp and the Silati goldfields, and is now in full working order.

SOUTHAMPTON.—The Southampton Electric Light Company have notified a reduction from 10d. to 8d. per unit, the reduction to take effect from the 1st January last.

TELEPHONIC ENTERTAINMENT.—On Monday evening last, by permission of the National Telephone Company, Mr. P. P. Kipping gave an interesting entertainment at the Lecture Hall of the Highbury Quadrant Church, London, N. Mr. Goring Thomas's opera, "The Golden Web," was successfully transmitted from the Lyric Theatre to the Lecture Hall, and at intervals during the evening cornet solos and recitations were received from Birmingham. The entertainment was so successful that it is to be repeated this (Friday) evening,

UPPINGHAM.—It is stated that this town is about to adopt the electric light.

UTTOXETER.—A request has been presented to the National Telephone Company asking them to establish a telephone centre at Uttoxeter.

WATFORD.—The Local Board have received a communication from Messrs. J. G. Statter and Co. announcing that it is proposed to form a company for lighting Watford by electricity. The Earl of Essex had consented to become Chairman. A Provisional Order is to be applied for on behalf of the Company. The clerk was instructed to advise the Board on the subject.

WHITEHAVEN.—A considerable correspondence between the Trustees and the International Okonite Company (Limited), as to the contract between the Company and the Trustees, has resulted in a notification that the contract is cancelled, except so far as to the liability attaching to the Company for any loss sustained by the Trustees in reletting and completing the contract. Fresh tenders have been advertised for, and have now been sent in. All other contracts in connection with the electric lighting scheme are being proceeded with.

WIDNES.—In connection with the proposed refuse destructor, which is to be put down for dealing with the town refuse, amongst the work which the machinery required for the destructor is intended to perform is the installation of the electric light.

WORCESTER.—The suggestion made in a letter from the Town Clerk regarding the lighting arrangements for the new workhouse buildings, that as the supply of electricity would be in the hands of the city authorities it was desirable that all public buildings should be lit by that illuminant, was agreed to by the guardians at their last meeting. It is expected that the City Council Electric Lighting Works will be in operation by the beginning of 1894.

YORK.—A Local Government Board inquiry was held in York last week on the application of the Corporation to borrow the sum of £6,000 for electric lighting purposes. It is proposed to include in the suggested alterations at the Corporation's Art Galleries the complete installation of the electric light throughout.

PATENT RECORD.

A record of Applications for Patents and Patent Specifications Published is compiled for this journal by MR. J. C. CHAPMAN, *Fel. Chartered Inst. Patent Agents, of 70, Chancery-lane, W.C., from whom any information on the subject may be obtained.*

APPLICATIONS FOR PATENTS

NOTE.—*The Specifications of Applications for Patents are not open to public inspection until after the acceptance of the complete specification. The names within parentheses are those of communicators of inventions, or where complete specification accompanies application an asterisk is suffixed.*

February 17, 1893.

3,572. J. E. WRIGHT. London. Improvements in printing telegraph receiving instruments. (Date applied for under Patents Acts, 1883, Sec. 103. 16th November, 1892, being date of application in United States.*)

3,573. E. TAUSSIG. London. Improvements relating to the extraction of metals by means of electricity and to apparatus therefor.

February 18, 1893.

3,590. E. PAYNE. London. Improvements connected with electrical conductors and their insulation.

3,666. W. LOWRIE. London. Improvements in and relating to electricity distribution.

3,675. E. L. MAYER. London. Improvements in and connected with telephone transmitters.*

February 20, 1893.

3,690. W. R. MORRIS. Birmingham. A combined ammeter and voltmeter.

3,720. G. ANDREOLI. London "Sourdine" for induction coils.

3,729. G. KAPP. London. Improvements in the supply of electric current for electric railway, tramway, and other purposes.

3,734. A. HOUGH and O. MARCH. London. Improvements in secondary-battery plates or elements.

3,743. E. H. LIVEING. London. Improvements in the preparation of carbon electrodes for electrolytic operations.

3,744. E. H. LIVEING. London. Improvements in the construction of carbon electrodes.

3,747. M. P. LLOYD. London. Improved process for the production of electrolytic copper.*

February 21, 1893.

3,757. A. C. BROWN. London. Improvements in thermo-dynamic motors.

3,775. C. DARRAH. Manchester. Improvements in and relating to electric lamps for lighting shop windows, and for other purposes.

3,779. W. STORR. London. A new or improved carbon holder for arc lamps.

3,804. J. WARING. London. Improvements in electrophotography.

3,817. A. W. SMITH. London. Improvements in armature cores.

3,831. J. E. KINGSBURY. London. Improvements in telephone exchange systems. (The Western Electric Company, United States.)

3,833. E. W. LLOYD. London. Improvements in electrical connections.

February 22, 1893.

3,883. W. LOWRIE. London. Improvements in and relating to the distributing of electrical energy.

3,953. E. T. HUGHES. London. Improvements in the construction of field-magnets for dynamo electric machines. (Cornelius F. Daniels, United States.)

February 23, 1893.

3,966. W. LOWRIE. London. Improvements in and relating to the distribution of electrical energy.

3,979. J. F. HOFFGAARD. Manchester. Improvements in telegraphic receiving instruments.

3,980. J. F. HOFFGAARD. Manchester. Improvements in telegraphic receiving instruments.

4,024. W. P. THOMPSON. Liverpool. Improvements in storage batteries or accumulators. (The firm of A. Vogel, Germany).

4,040. W. L. DAVIES. London. Improvements in type-writing telegraph instruments.

February 24th, 1893.

4,077. H. C. L. HOLDEN. Woolwich. Improvements in the construction of electrical measuring instruments.

4,086. J. H. WARD and M. H. GOLDSTONE. Manchester. Improvements in and relating to electrical switches partly applicable to other electrical appliances.

4,087. J. H. WARD and M. H. GOLDSTONE. Manchester. Improvements in and relating to terminals for electrical purposes.

4,091. F. H. NALDER, H. NALDER, W. S. CRAWLEY and A. SOAMES. London. Improvements in electrical measuring and other instruments.

4,093. G. HAYWARD. London. Improvements in electric belts, which improvements are also applicable to corsets or other apparatus.

4,096. R. KENNEDY. London. Improvements in dynamo-electric generators, motors and motor generators.

Hosted by Google

4,103. W. LOWRIE. London. Improvements in and relating to dynamo-electric machines.

4,106. L. EPSTEIN. London. A process for maintaining positive plates of secondary batteries in good operative condition.

4,111. F. W. GOLBY. London. Improvements in means or apparatus for establishing telegraphic communication with trains. (N. J. B. Etienne, France).

4,144. A. W. ARMSTRONG. An improvement in the electrodes of electric, galvanic, and other batteries.

February 25, 1893.

4,188. R. KENNEDY. London. Improvements in electric retouching of photographs, and in apparatus therefor.

February 27, 1893.

4,241. A. BEZANT. Liverpool. Electrical fog horn, thief detector and alarm.

4,267. T. E. WEATHERALL. Greenwich. An improvement in electro-plating.

February 28, 1893.

4,330. A. W. BOWDEN. London. Improvements in coupling joints for couplings of electric mains.

4,356. W. P. THOMPSON. Liverpool. Improvements in or relating to welding metals electrically. (Charles L. Coffin, United States.)*

4,360. W. P. THOMPSON. Liverpool. Improvements in the construction of plates for accumulators or secondary batteries. (La Société Electric Phoebus, France.)

4,363. W. P. THOMPSON. Liverpool. Improvements in or connected with electric railways. (James Hervey Bates, United States.)*

4,368. B. B. WARD. London. Improvements in electric arc lamps.*

4,390. E. CANNEVEL. Improvements in electric arc lamps.

4,416. D. F. FERNANDEZ. London. Improvements in dynamo electric machines.

March 1, 1893.

4,425. J. GILL. Halifax. Improvements applicable to gas and electric lamps for automatically turning the light up and down.

4,489. E. C. C. KROGH. London. Improvements in and relating to electric firearms.*

March 2, 1893.

4,546. J. B. MILLAR. Glasgow. Improvements in and relating to stepped pillars or standards for carrying electric lights, wire, and the like.

4,577. R. KENNEDY. London. Improvements in electrical distribution of energy and in apparatus therefor.

4,580. E. TYER. London. An improvement in telegraphic apparatus for railways.

March 3, 1893.

4,685. J. E. BATT. London. Improvements in recording and reproducing tapes for electrical ticket machines and other apparatus.

4,691. THE LITHANODE AND GENERAL ELECTRIC COMPANY (Limited) and J. T. NIBLETT. London. Improvements in the manufacture and production of elements for secondary batteries.

March 4, 1893.

4,726. J. A. HEAP. London. Improvements in the electrolytic production of chlorate of potash and chlorate of soda.

4,731. R. KENNEDY. London. Improvements in and relating to the measuring of electricity and in meters therefor.

4,734. S. G. KIRK. Nottingham. Electric fog signalling and the better prevention of accidents by collision on railways.

4,746. O. IMRAY. London. Improvements in incandescent lamps. (T. D. Bottom, United States.)*

4,759. W. M. MEREDITH. London. Improvements in electrical resistances.

4,772. T. G. MARSH. London. Insulating and preserving metal arms used for supporting electric telegraph insulators and for kindred purposes.

4,793. J. O. BROOKE. Wakefield. Improvements in the construction of the reel and battery-box in connection with portable electric bells.

4,818. C. M. DORMAN and R. A. SMITH. Manchester. Improvements in the construction of electric light switches and cut-outs.*

4,827. J. POLLITT, E. WIGZELL and G. MEDDINGS. London. An electric alarm for automatically signalling when lubricators are empty.

March 7, 1893.

4,869. W. J. GIBBS and S. P. FRANCHOT. Canada. Improvements in the process of obtaining chlorates of the alkalies, or of the alkaline earth metals by electrolysis.*

4,871. N. ROLLAND. London. Improvements in electric batteries.

4,874. H. F. FOSTER. London. Improvements in the transforming and conversion of electric currents.

4,910. E. L. JOSEPH and APPLETON, BURBEY, and WILLIAMSON. London. An improvement in electric switches.*

4,911. E. L. JOSEPH and APPLETON, BURBEY, and WILLIAMSON. Improvements in the construction of spring buffer connections for the holders of electric lamps.*

4,923. A. G. NEW. London. Improvements in conductors in telescopic standard lamp holders for electric lamps.*

4,938. G. S. RAM. London. Improvements in incandescent electric lamps.

4,941. J. TUMA and E. VON METSICZKY. London. Improvements in and relating to signalling on railways and in telegraphic relays for use in connection therewith, and for ordinary telegraphic purposes.

4,952. W. S. SMITH and W. P. GRANVILLE. London. Improvements in electrical relays and measuring instruments.

SPECIFICATIONS PUBLISHED.

All Specifications price 8d.

1892.

2,652. KLOSTERMANN. Voltaic arc lamps.

3,112. DE FERRANTI. Electric meters.

3,113a. DE FERRANTI. Conveying currents of high tension.

3,156. BRADFORD. Motive power engines.

3,240. LANG. Door handles, electrical insulators, &c.

3,427. SCHROEDER, C. A. J. H. and H. E. R. Electric arc lamps.

4,494. ANDERSEN. Electro-magnetic solenoid apparatus.

5,186. LENCZEWSKI. Electric arc lamps.

5,655. REES. Electric safety lamp.

6,088. BOEHM. Incandescent electric lamps.

6,465. HEYL. Secondary batteries.

6,720. KINGDON. Dynamo electric machines.

6,888. SPENCE. Electric conductors.

6,911. DAVY. Electric arc lamps.

6,989. MCMULLEN. Casings for electrical conductors, &c.

7,037. BELFIELD. Electric arc lamps.

7,252. CROMPTON and CHAMEN. Electrical distributing apparatus.

7,361. SPENCE and DEAKIN. Distributing electricity by alternate currents.

18,732. FAIRFAX. (Schukert and Company.) Arc lamps.

19,665. HOOKER. Telephonic apparatus.

20,009. SHARPLEY. Microphone.

23,805. BOMBE and SCHUCHARDT. Arc lamps.

23,906. PRENTISS. Incandescent electric lamps.

1893.

140. HARRIS. Storage Batteries.

336. BOULT (Walch). Lightning conductors.

387. BOWEN. Electric launch and sailing vessel.

471. ALLISON. (Hering.) Electric motors.

510. DE PASS. (Rice.) Electric transmission of power.

517 LAKE. (Weston.) Measuring electric currents.

518. LAKE. (Weston.) Measuring electric currents.

520. LAKE. (Weston.) Measuring electric currents.

1,356. SLOSS. Electric gas lighting.

1,502. THOMPSON. (Correns.) Secondary batteries.

COMPANIES' MEETINGS & REPORTS.

W. T. Henley's Telegraph Works Company (Limited).

The fourteenth ordinary general meeting of the shareholders in this Company was held at the Cannon-street Hotel, on the 17th inst., Mr. Sydney Gedge presiding.

The SECRETARY (Mr. White) read the notice convening the meeting. The report of the Directors and balance-sheet were taken as read.

The CHAIRMAN: I will move without any loss of time "That the report and balance-sheet now in the hands of the shareholders be, and are hereby, received and adopted." You will have already noticed, gentlemen, a difference in what has just taken place in our procedure between this year and last year, namely, that the notice convening the meeting was not read by Mr. George Sutton as formerly, but by Mr. White. The Directors thought that Mr. Sutton's valuable services ought to receive the recognition they deserve by his being elected to a seat on the Board. Under your Articles of Association that can be done. We can elect a gentleman to be one of your Directors and at the same time make him Managing Director. Mr. Sutton takes that position on the same terms, in all respects, as those on which he held the position of Secretary and Manager, with this exception, that while he is answerable for Mr. White's secretarial duties he will not perform them. I am sure you will give him a hearty welcome as a member of the Board of your Company. Well, gentlemen, we are like the happy nation which has not got much history. We are going on well and prosperously, and there is not much for me to say; in fact, I cannot do more than call attention to one or two things already mentioned in the report. Less than two years ago we borrowed £30,000 of "B" debentures for the purpose of discharging our floating debts, and the arrangement made was that, after the payment of 5 per cent. to the Ordinary shareholders, any surplus profits should be applied to the paying-off of these debentures. We have already paid off £18,000 in the course of two years, and there is a fair prospect of our being able to clear off the remaining £12,000, in other two years, and then the Ordinary shareholders will receive as a reward for the patience which they have exercised so many years considerable dividends. We have, no doubt, a great many rivals in our trade, but I am quite sure that there is none to surpass us, either in point of punctuality or in the quality of work performed. I am certain that there is not anyone that can beat us. As the report says, when we have finished our

Hosted by Google

new works we shall "then possess the most perfect workshop of its kind in the world." That is, perhaps, singing our own praises somewhat highly, but I think that we are stating nothing more than the truth.

Mr. JENKINS: It is not gas.

The CHAIRMAN: My friend Mr. Jenkins says this is not gas—it is electricity. I myself visited the works yesterday, and though I do not pretend to be an engineer or an architect, I could see how well arranged and complete the works are. Our engineer, Mr. Hatton, in making the designs for these works, and in constructing them, is acting, as he has always done, most efficiently and economically. I am assured, by those more competent than myself to judge, that your money is being well spent, and that, further, if our business is increased there will be so great a saving in the way in which we can do our work as to yield handsome returns to the Company. We should be able in these works to make cables which we have never made before, and for the reason of our inability to make these we have lost many orders—I mean, for instance, lead-covered cables. I do not know whether anybody here takes to the fashionable game of golf. If there be, I may inform him that we are manufacturing golf balls—a branch of business which we hope will continue to increase, and if you will send your orders to Mr. Sutton he will be glad to receive them. There is not much more to say. There is one paragraph in the report which is, no doubt, pleasing to you all: "It is interesting to note that no fault has been reported in any of the submarine telegraph cables laid by the Company since 1888." In 1888 we did lay a cable in which there was a fault. If we could at that time have given a substantial guarantee that the cables should not get worse, we should have received full payment of the contract money, but we were not strong enough to do it, and we were, therefore, mulct in a certain amount. I am happy to say that the cables have not become any worse, and are working as well as ever. Of course the company for which it was done made a considerable profit at our expense. Every shareholder has had the opportunity of looking at the balance-sheet, but I am quite willing to answer any questions that may be put to me. It is not desirable that minute facts relating to profit and loss account should be made known to our rivals in business, and, therefore, I will ask share, holders, who want any private information, to come to the office and ask for it. But if there be any question which I can answer without any inquiry to the Company, either I or some of my colleagues will answer it.

Mr. R. J. JENKINS, C.E., said that he had great pleasure in seconding the motion. In doing so he would not occupy much time. He would simply state with reference to the "B" Debentures that the paying off of these would have an immediate and a most important bearing on the interests of the Ordinary shareholders, because the actual saving on the £18,' 00 already paid off was equal to 1½ per cent. dividend to the Ordinary shareholders. As being somewhat responsible as a delegation from the Board, General Hutchinson and himself, having a knowledge of engineering, had taken a great deal of care to watch all the expenditure made in connection with the extensions at the works. The whole of the capital and a considerable amount of the additional sums which some of the shareholders were good enough to supply by taking up the Preference shares last year was being laid out in improving the works, and would enable them to take not only more important contracts, but to effect immense savings in some classes of work which they were in the habit of executing. They were also providing a siding which would save a great deal of money by reason of the fact that they would get all their goods brought into the works direct from the Great Eastern Railway, instead of having to convey them by carts and vans. They had opened a branch establishment in Melbourne (Australia), and although it was known to all City men that Australia was now under a cloud, more particularly the Melbourne district, they had received from their agent there—a most experienced man, who had been connected with electrical work for important firms—returns of considerable sales effected there, and assurances of still more business. They had, fortunately, sent out goods which appeared to command a ready sale, thanks to their Managing Director, who sent out to the colony to ascertain the particular kind of articles wanted there. He had no doubt they would very shortly have good returns—certainly as soon as the cloud had lifted from the Australian markets. It would be seen that they had completed the manufacture of the Bahama and Florida cable last year, and having done so, they were able to arrange for making an effective repair of one of the Western Union Telegraph Company's cables. That produced some revenue to the Company, but they did not value it so much for the revenue it produced as for the fact that it at once established the Company in the position of cable repairers, and made it known that they were able to undertake such a class of work, and on better terms than were able to be previously negotiated. The Chairman had said that the accounts had been open to the inspection of every shareholder. The system they adopted in respect to them was that laid down in their Articles of Association, but they would be glad to answer any questions which might arise in respect to the accounts.

Mr. HUGHES-HUGHES thought that it would be of more interest to the shareholders to have a printed balance-sheet than an invitation to inspect it at the office.

Mr. FIGGESS said that he approved of the present arrangement and supported the Directors.

The CHAIRMAN said that, while the Board would take into consideration this suggestion, they thought that at present, with all due deference to Mr. Hughes, no sufficient reason had been given to show cause why they should alter the course they had hitherto pursued. He then proposed the payment of a further half-year's dividend on the Preference shares at the rate of 7 per cent. per annum, and a dividend for the year at the rate of 5 per cent., free of Income Tax, on the Ordinary shares, leaving a balance of £13,425. 9s. 4d. to be carried forward.

Mr. BALL seconded the motion, which was carried *nem. con.*

Mr. LAMONT proposed the re-election of Mr. Sydney Gedge to his seat at the Board.

Mr. GLANVILL seconded the motion, which was cordially carried.

The CHAIRMAN, having briefly expressed his acknowledgment,

Mr. HUGHES HUGHES proposed, and the Rev. R. K. HASLEHURST seconded, the re-election of Mr. R. J. Jenkins, the other Director retiring by rotation.

The motion was carried unanimously.

Mr. JENKINS, in returning thanks, said that he had endeavoured to make his 13 years' service of value to the Company, and he trusted to make them of still greater value in the future.

Mr. FIGGESS proposed the re-appointment of the Company's auditors, Messrs. Ball, Baker and Co., which was seconded by a SHAREHOLDER, and agreed to *nem. con.*

Mr. R. J. JENKINS proposed, and a SHAREHOLDER seconded, and it was carried unanimously, that a vote of thanks be and is hereby given to the Works Manager, Mr. R. J. Hatton, and the staff at the London Office and at the Works.

The meeting concluded with a vote of thanks to the Chairman and Directors for their services.

Woodhouse and Rawson United (Limited).

An extraordinary general meeting of this Company was held on Monday at the Cannon-street Hotel. In the absence of Sir Rawson Rawson, the Chairman, through a domestic bereavement, Mr. Samuel Pope, Q.C., presided.

The SECRETARY having read the notice calling the meeting,

The CHAIRMAN said that his duty in the chair would be best performed by putting the meeting as exactly as he could in possession of the facts as regarded the present position of the Company. Since they had met together to receive the report of the Committee which was appointed at the annual general meeting, a receiver had, at the instance of the debenture-holders, shareholders and the creditors, been put into possession of the assets of the Company as a receiver and manager. The Directors did not see the way to resist that appointment, nor did the trustees for the debenture-holders. In fact, Sir Rawson Rawson himself, as representing the debenture stockholders, felt that it was necessary that if a receiver were appointed he should represent the whole of the interests of the Company, and not one particular class of interests exclusively. Therefore the receiver and manager was now in possession of the assets of the Company representing the debenture-holders, the debenture stockholders, and also the shareholders. That gentleman had been, by authority of the court, enabled to raise a small sum of money for the purpose of carrying on the business of the Company to a small extent, in order that it might not subside altogether. In addition to the receiver now in office with the sanction of the court, there were upon the files of the court two further petitions praying for the appointment of a liquidator under a compulsory winding-up, and, therefore, as those petitions stood over and would not be heard until April 11th, the Directors had thought it important that the shareholders should meet to discuss the position, in order that they might decide whether in the interests of all parties it was desirable that the concern should be broken up, or that an effort should be made to keep it together in the hope that something might be done to minimise the loss of all concerned. He did not desire now to make any comments on those petitions, but he must venture to say that it appeared to him that the eagerness to break up the concern was proportionate to the smallness of the stock that each individual desiring to do so held. The first petition was on the part of a small stockholder to the extent of only £250, and it appeared to the Directors—certainly to himself—that those who had a larger stake in the concern than that should have an opportunity of deciding what was the best way of dealing with the property, instead of leaving it to somebody who, after all, had only a limited interest in it. He did not know from whom the second petition came. It would be remembered that the report of the Committee pointed out that if the assets of the Company were realised in an intelligent manner, there would probably be sufficient to pay the liabilities of the Company. [A Voice: How about the shareholders?] He would come to that. The report of the Committee pointed out that there was a fair chance that the debenture-holders would be paid off, but that if the concern was broken up altogether and the assets realised at broken-up prices, the ordinary shareholders had not much chance of getting anything out of it; therefore, the question was one for the shareholders to decide whether something should be done in the way of reconstruction, or in some other manner, to save some of the assets of the Company for the benefit of the shareholders. This seemed the question that they had to decide. It would be observed that they had been called together with the formalities which were necessary to make their resolution a binding resolution of the Company. As far as the Directors were concerned, if the shareholders saw their way under new management to reconstruct the Company, they would do all that they could to facilitate and assist such reconstruction. Speaking for himself, he thought that it was essential that, in any reconstruction scheme, those who found the sinews of war for giving it effect should have the nomination of those who would have the administration of the affairs of the new Company. He thought that he spoke the unanimous feeling of his colleagues in saying, that, in the event of the shareholders desiring such reconstruction, their seats at the existing Board would, of course, be placed at the disposal of the shareholders, who would be asked to appoint new Directors. It appeared to the present Board that no scheme of reconstruction could be likely to be acceptable to the shareholders, except upon three conditions. It seemed to them, as it appeared to the Committee who met them on the last occasion, that it would be idle to expect shareholders, or anybody else, to put more money into a concern if its profits were to be swallowed up either in the payment of liabilities or in the payment of the burdens which the debenture debt entailed. The Board, therefore, thought that if any scheme of recon-

Hosted by Google

struction was possible, the first thing to ascertain was whether there was a good background of business worth preserving. Now, as far as he knew the facts, there was; but they must satisfy themselves, and not take the statement from his mouth. He could only take it of course *ex relatione* from those who knew about it. The report of the Committee estimated roughly, without going into details, that the industrial part of the business might command about £11,000 profit per annum, which would be enough to pay off only the debenture interest, and, therefore, would leave nothing to be divided among the shareholders. The general manager of the Company took a more sanguine view of the situation than that. That gentleman judged, from the business which he had been compelled to refuse since their general meeting in December, that the profits would be nearly three times that amount. Of course, he was only stating that that was the manager's sanguine expectation. But the receiver had, he believed, also formed his judgment of the possibilities of the business from the experience he had gained in the meantime, but he (the speaker) had not got information as to what that opinion was; but whether the income was £30,000, or £11,000, or anything between these amounts, it was clear that those who should have the first claim on the profits were those who subscribed to carry on the business. The second condition appeared to be that the old debts against the assets of the Company should be left without change of their relations, and, further, that in any reconstruction, as he was most bitterly sensible, the shareholders ought to insist on entirely new management for the industrial part of the concern. Well now, the question was whether, on some such lines as these, the shareholders thought it would be better to break up the Company—which, of course, meant the immediate realisation of the assets—or whether an attempt should be made in order to see whether a reconstructed Company might save something for the shareholders, who otherwise, he was afraid, would get nothing. If that were the view of the shareholders the resolution which was in the circular convening the meeting would be the resolution which they would have to pass, and which he would move:

"*That it has been proved to the satisfaction of this meeting that the Company cannot, by reason of its liabilities, continue its business, and that it is advisable to wind up the same, and accordingly that the Company be would up voluntarily, and that there be conferred on the liquidator or liquidators all the powers which, by virtue of the Companies Acts, 1862 to 1890, can be conferred on the liquidators.*"

He concluded by inviting the Company's Solicitor to explain the general character of the scheme of reconstruction which commended itself to the minds of the Board.

A short discussion took place as to whether this course was necessary, but eventually, by a show of hands, it was agreed to.

The SOLICITOR said that the suggested scheme of reconstruction was that a new Company should be formed, which would take over the assets of the existing Company, but would take them over in such a way that, whilst the charges of debenture-holders and debenture stockholders on those assets would remain fixed, the new Company would not incur any personal liability to the debenture-holders or the debenture stockholders. The new Company would take these assets, use them, and realise them, pay the proceeds to the receiver or liquidator of the existing Company, who would distribute them among the debenture-holders and debenture stockholders, and the new Company would get a certain profit in turning over the assets and realising them. By that means the existing Company would retain whatever working capital was put into it intact and unfettered by the existing Company in any way. The ordinary creditors in the existing Company would, of course, have to be met in some way, and the proposal was that they should be offered preference shares in the new Company, and if they did not accept these shares that they should retain their present position. With regard to the bringing in of capital to the new Company, and dealing with the shareholders of the existing Company, there were two schemes, with regard to which the Directors had not yet decided which was the better. One was, that the working capital should be acquired by the issue of shares, which would be paid in full by the shareholders, who should receive some sort of security in the way of income bonds, or something of that kind, which, whilst imposing no further liability upon them, would give them the right to the surplus profits of the new Company. The shares or income bonds, whatever they might be, would have to be offered first to the preference shareholders of the existing Company, and those that were not taken up by the preference shareholders would be offered to the ordinary shareholders. This was necessary because, of course, the former had a first claim on the assets of the Company and dividends. He did not think that he could go further into details now, because the scheme was before counsel for consideration, and it was one which required a great deal of thought and care to work out.

Mr. SWAIN wished to know what stake each Director had in the Company. It was all very well to talk about probable profits, but taking their balance-sheet he could see no visible means of a dividend. There was not one thing to show it. The financial business had resulted in an utter loss, and the industrial part of it had been carried on at a sacrifice. He wished before the Directors were released from their post to know what claim the debenture-holders, and debenture stockholders had on the shares of the Company.

The CHAIRMAN said that the amount of debentures and debenture stock was £142,000—a claim on the assets of the Company, not on the shareholders.

Mr. SWAIN said that the scheme was a very easy means of letting the Directors escape from their responsibilities to let them form a new Company.

The CHAIRMAN rejoined that whatever might be done it would not relieve them from a single responsibility.

Dr. DUNCAN read a number of extracts from the prospectus of November, 1891, and subsequent reports of the Directors, upon the strength of which he said he had invested his money in the Company. He strongly condemned the conduct of the Directors, and thought that the whole of their actions in regard to the Company should be made the subject of a searching investigation. In addition to this, he would ask all those shareholders who took shares on the strength of the new prospectus referred to, to support him in his determination to bring an action against the Directors for the false statements contained therein. He proposed that the Company, which was rotten to the core, should be judiciously wound up, and that the whole concern should be investigated in a proper manner.

Mr. W. S. SQUIRE (chairman of the Committee of Investigation) addressed the meeting at some length, dealing principally with some of the facts brought out in the report of that Committee, published in *The Electrician* on March 10th. He said that, however much the Directors might quibble about each individual item to which the Committee had referred, the solid fact remained that they had induced the shareholders to believe for two years that the Company was doing well and making substantial profits, whereas at the end of the third year of its existence they had to confess that they had muddled away the whole of the ordinary and preference capital. A great deal had been said about their valuable lamp patents, but it turned out, so far as the register of the Patent Office disclosed, that those patents were not in the name of the Company at all. There might be an agreement to transfer them, but, as a matter of fact, they had not been assigned. Another fact was, that when any agreements were signed, they were signed for only one-half interest in these lamp patents, and anybody who knew anything about patents at all would tell them that half of a patent, unless under certain special circumstances, was practically of no value. These and similar facts had, of course, influenced the Committee very much in arriving at the value they put upon the patents. He might mention that in his opinion, and he might say really in that of the other members of the Committee, the action of the Directors in the matter of the Phœnix Trust and Epstein affairs looked very much like an excuse for paying dividend out of capital. He did not say it was, but it appeared very much like it. With regard to the proposal for reconstruction, it was extremely difficult to give an opinion; but the only way in which the new Company could possibly do any good was by ruthless concentration.

Mr. ABRAHAM quite agreed with Dr. Duncan with reference to the proceedings of the Directors and their liability. The Directors, from Lord Aberdare down to Mr. F. L. Rawson, were undoubtedly liable. He condemned the conduct of the Board in respect to its agency business and the formation of companies.

The CHAIRMAN reminded the speaker that in each case when a company was being formed, the shareholders had received a circular detailing the circumstances and soliciting subscriptions.

Mr. ABRAHAMS was very glad to hear that proceedings were likely to be taken against the Board, and that the meeting was likely to support such a course. He would go farther, and say that it would be a public scandal if proceedings such as had taken place in connection with the Company in the past were not investigated, and if the Directors were to go free. The large shareholders were bound to stand by the small ones in order, if they could, to increase the assets of the Company by making the Directors liable.

After some further discussion,

Sir JOHN STOKES seconded the resolution.

Dr. DUNCAN moved as an amendment:—

"*That the Company be wound up compulsorily.*"

Mr. BOND said that, as a considerable shareholder, the liquidator of a Company now under voluntarily liquidation, and as a barrister, he wished to point out that it was always possible to turn a voluntary liquidation into a compulsory one, and, therefore, that to pass the resolution would not prejudice their rights in any way. By a compulsory liquidation there was very little chance of the ordinary shareholders getting anything, whereas if it were voluntarily carried out, there was a probability of their getting something returned to them.

Mr. LESLIE, representing the receiver, said that the latter had expressed his opinion that there was good work to be done in connection with the Company at remunerative prices as far as he knew. The same gentleman had expressed his surprise that there was so much work to be done. He told the shareholders frankly that if they went into compulsory liquidation they would not receive a penny.

Mr. BACON, one of the members of the Committee, advocated voluntary liquidation as the best possible course to follow.

Colonel POE animadverted strongly on the conduct of the Directors, on the strength of whose names he alleged that many of the shareholders had subscribed to the capital of the Company.

Mr. MORRISON also recommended voluntary liquidation.

Mr. PILLING (Manchester), who investigated with the Shareholders' Committee the affairs of the Company, also addressed the meeting, strongly condemning the action of the Board in respect of the manner in which they had dealt with the £75,000 guarantee fund and other items. At the same time he admitted that voluntary liquidation was the only prudent step to take in the circumstances.

The CHAIRMAN then put the amendment to the meeting, and declared it lost. The original resolution was afterwards put and declared carried without a dissentient.

Mr. BACON proposed the appointment of Mr. Pilling as liquidator.

Mr. SQUIRE seconded the motion. Both gentlemen paid a warm tribute to Mr. Pilling for the painstaking way in which he had assisted the Committee of Investigation in getting up the facts presented in its report.

Mr. WAIN proposed Mr. Young, of the firm of Messrs. Turquand, Youngs and Co., for the post.

A SHAREHOLDER seconded Mr. Young's appointment.

Hosted by Google

The CHAIRMAN having invited the sense of the meeting as to which gentleman should be appointed, declared in favour of Mr. Pilling.

Mr. WAIN thereupon demanded a poll, which was at once taken.

In the end the voting was as follows:—For Mr. Pilling, 10,229; for Mr. Young, 7,710. Majority for Mr. Pilling, 2,519.

The proceedings then terminated.

Elmore's French Copper Depositing Company (Limited).

An account appeared in *The Electrician* of the 17th inst. of a meeting of the shareholders of the parent Elmore Company held on the 16th inst., and during the present week a report has appeared from the Committee appointed to investigate the Company's affairs, and to ascertain its exact position. It will be remembered that this Committee were fortified in their investigations by the assistance of both an electrical and a financial expert, and that Mr. A. Le Neve Foster was appointed in the former capacity, and Mr. Burnside as financial adviser. A circular issued by the Committee deals with the financial position, but it is with Mr. Foster's report that we are chiefly concerned. This report is as follows:—

"I have visited the Company's works at Dives and carefully examined everything in connection with the manufacturing business. The works are of a substantial character, well-built, and apparently suitable for the manufacture for which they have been designed. They appear to have been constructed in a somewhat costly manner, more especially as far as the plant is concerned. The works and plant have been erected for a monthly output of some 300 tons. The engines and dynamos are in duplicate and triplicate, and on a very extensive scale. Up to the present time the output has been comparatively small; hence this plant has been worked at a great disadvantage. The system of construction and working of the deposition tanks with their electrical and mechanical arrangements (this being the part embraced by the Elmore patents) were presumably constructed in accordance with Mr. Elmore's advice, aided by the experience gained by the French Company from the costly experimental work done in Paris. However, on the manufacturing at Dives being commenced, great alterations had to be made to the machinery before marketable tubes could be produced by the Elmore process. The apparatus first erected for giving motion to the mandrils in the depositing tanks caused considerable trouble, and had to be entirely remodelled before continuous working could be carried on. A large number of the tanks are still fitted with the old gear, which will require altering before the tanks can be used. The new driving gear has, I believe, been patented by M. Secretan in France, and is a marked improvement on the original plan. The original burnishers were found unsatisfactory, and new arrangements for these had also to be constructed. When it is remembered that the mechanical machinery for the entire 264 depositing tanks, covering a floor space of some 60 by 90 yards, had to be completely re-modelled, much of which there still remains to be done, it must necessitate a heavy outlay. This outlay could have been avoided had ordinary caution been exercised and the plant in the first instance tried on a less extensive scale.

I gathered from M. Secretan and others at Dives, that the system was constantly breaking down, and had in a great measure to be re-constructed before anything like saleable tubes could be produced. To-day the capabilities of the depositing tanks that are in working order are equal to some two tons per day of 24 hours. The remaining plant requires considerable alterations and outlay before they are capable of producing the 300 tons per month for which they were originally designed. These facts would seem to be inconsistent with the prospectus of the company, from which it would be presumed that the experimental stage had been passed. An extensive plant has been erected for the manufacture of copper plates, and also for wire drawing. This seemed to me to be undesirable, as the margin of profit on this manufacture is very low when compared with tubes. At the time of my visit neither the manufacture of plates or wire had been started. The electrical arrangements, as before mentioned, were planned for an output of 300 tons per month, consequently are now being worked most uneconomically. A very serviceable plant has been put down for drawing the tubes, by which means they can greatly reduce the cost of expensive mandrils that would otherwise be required for manufacture under the Elmore process. The plan of subjecting the tubes to the drawing process was, I believe, when first erected, objected to by Mr. Elmore as unnecessary. Had this plant not been put down, the orders that have already been executed by the Company could never have been undertaken. The drawing is done at comparatively small cost, and obviates delays in execution of orders. It allows the depositing tanks to be worked constantly on certain stock sizes, facilitating greatly the electrical arrangements, whilst at the same time it improves the quality of the copper.

The following estimated cost of production is for an output of 60 and 100 tons per month. My estimate is calculated upon the expenses at the works only, not including any allowance for depreciation, interest on money expended in patents, renewals and repairs of buildings and plant, &c., rent, taxes, and expenses in Paris and London. The expenditure is based upon the figures I obtained from the books at the works. An expenditure of £1,200 per month for salaries, wages, coal and sundry materials, but excluding the cost of raw copper, should prove sufficient, with judicious management, to cover a steady output of 100 tons per month. With the smaller output of 60 tons there would be little, if any, saving with the present arrangements. To these calculations I have added the value of silver and gold that may be found in the sludge of the depositing tanks. The value of this depends entirely upon the nature of the ingot copper treated. If suitable argentiferous brands of copper are used, and careful means are adopted to collect the sludge, the additional profit may readily reach as much as £7 per ton of copper treated, or even more. It is presumed in these calculations that a steady sale can be effected of the quantities in question.

Estimate of Manufacturing Gross Profit.

Tons of raw copper treated per month.	Cost of copper, manufacturing expenses, salaries, wages, &c., per month.	Cost per ton, including raw copper.	Gross manufacturing profit, including an estimated value of gold and silver recoverable of £7 per ton.
Tons.	£	£	£ s.
60	3,960	66	16 15
100	5,800	58	25 15

In the above estimate raw copper is taken at £46 per ton, sale price of tubes at £80, and of electro-deposited scrap copper at £50.

In working the Elmore system as the plant is at present arranged, it is most important that a regular output from the depositing tanks be maintained, and my figures are based upon this assumption. The manufactured copper tubes that I inspected and tested were of excellent quality, and certainly superior to ordinary commercial solid drawn tubes, and should command a ready sale at market prices. The organisation of the works at Dives was good, and the heads of departments appear to be thoroughly competent men. For works of this size the monthly expenditure is by no means excessive, whilst the administration expenses at both London and Paris appear to me to be out of all proportion to the small amount of copper that has been treated, or even for a much larger output. Respecting the value of the works at Dives, it would have been impossible for me, with the time that was at my disposal, to arrive at anything like a fair valuation; but it is very certain that in the event of a forced sale they would realise very little indeed in comparison to the immense sums expended on them.

The Elmore system, when purchased by the Company, appears to have been far from perfect, and had this fact been realised prior to the construction of the works, the heavy expenditure of the shareholders' money, incurred with conspicuous lavishness, would have been avoided."

It will be seen from this report that Mr. Foster has gone thoroughly into the value of the Elmore process, and, as was to be expected, this report was made the basis of many severe strictures at the meeting of the Company held on Wednesday last, of which an account is given below. It will be noticed that reference is made to some new driving gear for giving motion to the mandrils in the depositing tanks, which has been patented in France by M. Secretan, but no mention is made as to whether the patent is the property of the French Elmore Company. On the 20th inst., and prior to the meeting of shareholders on the 22nd, the Directors issued a reply to the circulars of the Committee in which they set out their view of the financial position of the Company, which, it is needless to say, materially differs from that of the Committee, and in regard to Mr. Foster's report an abstract of their reply is as follows:—

"The discrepancy referred to in paragraph 2 does not appear to us to exist, as the advantages set out in the original prospectus have all been confirmed. With regard to the cost of manufacture, the Directors estimated the cost at one penny per pound, while Mr. Foster calculates that, when turning out 25 tons a week, the cost would be a trifle over a halfpenny per pound, after making an allowance for the gold and silver in the copper. This calculation is based upon the prices obtained for the smaller tubes, with which M. Secretan has very rightly commenced manufacture, and does not take into account the higher prices which may be commanded for exceptional sized tubes and other work. The unsatisfactory results of the seven months' working, referred to in paragraph 3, are due to the smallness of the average output caused by the want of working capital to purchase copper. The expenses of a small output are almost as heavy as those for a large output, a fact sufficient to account for the large manufacturing profits that Mr. Foster estimates when the output is increased to 100 tons per month. The Directors think that Mr. Foster takes an exaggerated view of the cost of the modifications. A considerable number of the tanks have been modified, and the exact cost of modifying the remainder is thus known. The Directors conclude by saying that their last published estimate showed a profit per ton of finished tubes taken out of the tanks; Mr. Foster's estimate of profit is per ton of raw copper deposited, the difference between the two being copper sold as electrolytically-deposited scrap."

A meeting of the shareholders who subscribed to the preliminary inquiry instituted by Sir Thomas Farrer, Bart., Mr. William Saunders, M.P., and Mr. Samuel Storey, M.P., into the affairs of the above Company, was held on Wednesday, at the Cannon-street Hotel.

On the motion of Mr. SAUNDERS, Mr. Storey was voted to the chair.

The CHAIRMAN said that the circumstances under which they were met were familar to them all, and, therefore, he need not dwell upon them at length, but merely state them. Some of the shareholders were dissatisfied with many matters relating to the French Elmore Company. Their dissatisfaction pointed in four directions. First of all, they were dissatisfied with the absolute non-fulfilment of the promises made originally and at a later time; second, they felt a business-like objection to the method in which the works had been laid out for an enormous output before there had been practical proof that a smaller output could be produced with profit; third, they were horrified to see the loss on working during the months of last year, when the works were busy; and fourth, they were brought to bay by the fact that the Directors admitted that it was absolutely impossible to go on unless they could get a large sum of money, which he practically put at £50,000. That being their state of mind, Sir Thomas Farrer, Mr. Saunders, and himself took upon themselves, as shareholders, to send out a circular asking other shareholders to join them in ascertaining all the facts of the case. He was glad to say that the responses they received were very hearty and numerous; and by means of the funds placed at their disposal, they got Mr. William J. Burnside to make a financial and general report on the affairs of the Company, and

Hosted by Google

they also sent Mr. A. Le Neve Foster to France to see for himself the state of matters and report to them thereon. On receiving those reports from these gentlemen they made a report on their own account, and he believed that statement had gone to every gentleman present. Inasmuch as it had been sent to them he presumed it would be taken as read. A similar course would, he thought, be taken in regard to Mr. Foster's report. Sir Thomas Farrer, Mr. Saunders, and himself had acted in a perfectly fair and above-board fashion. They had not gone behind the Directors or assumed that they were wicked men. They had put themselves in communication with the Directors, and he was glad to be able to say that they had found the greatest willingness on the part of Major Jones and his *confrères* to give them what information they could.

The circular letter sent to the shareholders and Mr. Forster's report were taken as read. Mr. Burnside's report (which was of a purely financial character) was read *in extenso*.

The CHAIRMAN then read two letters—one from a gentleman whose name was not disclosed, urging that the only way to keep the Company alive was by forcing the creditors to come to terms by raising the necessary money on debentures to meet their claims, and then appointing a Committee with a view to its forming some plan of reconstruction. The other letter was from Mr. W. Elmore, repudiating certain statements contained in the reply of Mr. Foster. The Chairman then went on to say that what they ought to try to do on that occasion was not to indulge in complaints or condemnation of anybody as to the past (although the time might come when that would be necessary), but rather, as men of common sense, to address themselves to the problem, how could they make the best of the Company. He did not know whether every gentleman present would agree with him, but he would put the position of affairs as he saw it. First of all he would put it in this way. He would say that there were three courses, and three courses only, open to them at the present time. The first was to go on. That was the advice which Mr. Rawson had given to them; that was the advice which the Directors would fain give to them; that was the advice which he would tender to the meeting, if he could be satisfied on two points, first, where was the money to be found to go on with, and second, was there a reasonable business guarantee that it could be effectually used to produce profits. Now, he spoke to gentlemen who would be prepared to find the money. Mr. Rawson would give them a good handsome sum, and Mr. Elmore too. He would like to ask this question. How did it come about that this money was wanted? Mr. Burnside had put the thing very clearly. The money was wanted at present because the money already supplied had been grossly misapplied and wasted. He would make two quotations in support of that. He had been looking through the statements made, not when the original Company was founded, but at a much more recent period. There was a report of the first general meeting on January 9, 1891, and he would like to read what the Chairman said then. "The Board had raised £50,000 additional capital on Six per Cent. Debentures issued to the parent Company in order to carry out Mr. Elmore's suggestion to increase the plant to the extent of being capable of producing 300 tons per month." M. Secretan, in his speech, stated that within three months—that was to say, from January, 1891—"we shall be in a position to turn out 370 tons of copper articles per month, the sale of which is absolutely assured." In a circular issued by the Chairman of that period it was announced that the works were completed and capable of turning out 80 to 90 tons a week, which was practically the same as 370 tons a month. The manager was very enthusiastic about the financial results, and stated that the demand far exceeded the total output of the works. Well, now, if there had been any sort of truth in these statements, it was very evident that the shareholders would not have been in their position to-day. But the fact remained: Never since that time had they got anything like 20 tons per week out of the works. He was told that 14 tons was the largest number they had ever been able to take out. Therefore he said that, unless the gentlemen were bad business men—men not to be trusted in business, although they might be trusted in other ways—different results should have been achieved. He would say one word about M. Secretan. He had not a word to say about that gentleman personally. He thought that M. Secretan was a very worthy and clever man, but begged to say that he was no business man at all. The reason why was this: If they went into a business of any kind about which there was any doubt, they would go into it like common-sense Englishmen slowly and surely. They would put down a portion of the plant, and if they were satisfied that it would be sufficient to provide them with profits, then they would put down more plant. But what M. Secretan did was, he put down huge plant, which in practice he had never been able to use, and the twofold effects were, first, that the money which they wanted was sunk in unused material, and there was an additional charge on the Company's income for the interest of that money which was giving them no return. Was there any possibility from any source of getting £50,000? And was there any gentleman, if they did get the money, who could work the business in France in a way by which they would produce good results? They might drift on as they were doing, losing largely as they did last year. They would drift on with their creditors pressing them, and the Directors meeting the pressure by renewing bills at ruinous and extortionate interest. The facts could be proved, but practically it amounted to that. Some gentlemen wanted £8,000 from this Company. The Directors could not pay, and they gave bills that ran for a year which would have cost 25 per cent. He was not going to pin himself or the meeting to the precise figure; but he could state definitely upon the examination of Mr. Burnside that these bills had been renewed at an enormous rate of interest. Every such additional charge by the creditors diminished to that extent the chances of the debenture holders and ordinary shareholders getting anything at all, and if that were the sort of thing that was going on they might find the preferential claims of creditors so great that they would absorb all the available resources of the Company. That was an argument too strong to be resisted against any policy of drifting as the Directors had been doing during the last few months. What was the alternative, if they could not raise the money and carry on the business, and if they did not want preferential claims to be created which would diminish their chances of getting anything? A third course was a disagreeable one, but it must be left to the shareholders who were interested and who had paid hard cash for their shares—they must liquidate in the wisest and best manner they could. They must not leave the liquidation to those who had reaped the profits of the thing, but put it into the hands of those who had suffered loss, and so in that way make the best attempt they could to get out of a bad business. He had unfolded the facts, and had spoken with perfect frankness to the meeting. Personally, he would not consent to go on as they were doing. He would not allow the Company to drift and create such preferential claims; but he would be willing to listen to any proposal which would amend the concern, so that they might get something out of it.

Major JONES (the Chairman of the Company) said that he had come prepared to place before them the manner in which the money that the Directors had dealt with had been spent, but he found that this was unnecessary, because Mr. Burnside, in his report, practically had given them the same figures which he (the speaker) would have given. Passing on to criticise Mr. Foster's report, he thought that Mr. Foster had clearly exaggerated the amount of money spent on alterations. As to the Elmore process, there was no question that when they purchased it, it was in operation on a very considerable scale at Leeds, where they were making tubes of large diameter of excellent quality.

A SHAREHOLDER: At a profit?

Major JONES said he did not know. He was only saying that the process was actually in operation. M. Secretan, it would be remembered, in order to meet the regular current demand for tubes, thought it would be best to commence with small-sized ones, which were not being manufactured in Leeds, and this required a certain amount of experimental work which, of course, increased the preliminary expenditure before they were in a position to commence regular manufacture. As to the buildings and plant, they knew, as a matter of fact, that the expenditure on these was small, and although Mr. Foster seemed to think that a large amount of money was unnecessarily expended on these, the Directors had reports from others who held a very different opinion. Although some few hundred pounds might have been spent on external decoration, yet on the whole there was nothing to be characterised as being in any way extravagant or wasteful. As to the future, there was no doubt that if they were called on to meet their liabilities they could not do so; but, as was shown in the circular which they had sent out, the £92,325 of liabilities included £39,000 which had been advanced by the Foreign and Colonial Elmore Company, and was secured by a second mortgage, of which there was no pressure for payment. After dealing with some of the other figures in Mr. Foster's report, he went on to say that that gentleman had calculated the profits on an output of 100 tons per month, which was just about one-third of what the works were capable of turning out if they were to carry them on. If, however, they were able to place the remainder of the new debentures, the interest payable on them would be £7,000 a year, the interest on the second mortgages was £9,400, and if they took £15,000 for depreciation and other charges referred to in Mr. Foster's report, there would be a margin of profit on an output of 100 tons a month sufficient to pay the interest on the preference shares and if they were to go on to 150 tons a month, they calculated, after paying all the standing charges, that there would be sufficient, not only to pay the interest on the preference shares, but 5 per cent. on the ordinary shares. Another point was that if they had money and would go on with the business they could not only make a profit, but re-establish confidence in the Elmore process, they would be able to get money to meet liabilities on reasonable terms, and the ordinary shareholders, who if they went into liquidation just now would lose everything, would be in a position to raise money on their holdings. If the shareholders would find the money he was convinced that the Company could soon be placed in a very much better position and the shareholders would make something out of it. No cash in the way of fees to the Directors, except in the case of the Managing Director, had been drawn for nearly two years.

Mr. GLADSTONE: What amount would you be prepared to put in?

The CHAIRMAN asked, if the shareholders were willing to find some money, how much the Directors were prepared to give.

Major JONES said that he was a poor man, and what he would lose over the Company was over £3,000; but if the shareholders were willing to take up these preference shares and enable the Company to go on, he was prepared to put in his proportion of the fresh capital.

Mr. F. L. RAWSON afterwards addressed the meeting at considerable length, and said that there was still another course open to them besides those suggested by the Chairman, and that was that they might sell the undertaking to France. He had a proposal which had been put into his hands before the meeting, the details of which he fully set forth. He strongly urged them not to wind up the Company, which, he said, would result in absolute loss to the ordinary shareholders.

Mr. STRETTOLL warmly expressed his confidence in the Board of Directors.

Mr. FOSTER said that his estimate of making copper was not an estimate of what was being done at present; it was an estimate of what copper could be made for if proper works were constructed and proper expenditure incurred. As regarded their being able to turn out 14 tons a week, his own opinion was that they could not do it commercially, and certainly they could not turn out 60 or 100 tons a month at a profit. He must say that he thought that a very large sum had been spent on the works, and that a much larger sum would still have to be spent upon them. It seemed to him that the whole work of the Directors had been nothing more or less than a huge experiment. He would like that to be really understood.

Hosted by Google

Dr. HEDLEY, referring to the prospectuses (from which he made several quotations) issued by the Directors, said that these documents directly misrepresented the condition of the Company, because the Directors were either totally ignorant of the business they were conducting, or else they issued those prospectuses with the object of deceiving the public.

Mr. SAUNDERS, M.P., said that no proposal had been put before them but the old cry for more capital, and that they could not buy a ton of copper. Was it common sense to suppose that it was the want of copper that stopped their production when they had in their stores copper to the value of £20,000, and they were only producing £1,000 worth of manufactured copper per month? He ventured to say that such a statement was the strongest condemnation of the management of the Company that possibly could be made. Mr. Rawson repudiated any responsibility for the management. He (the speaker) was surprised to hear that, because he must confess he had come to the conclusion that Mr. Rawson was the mainspring of the whole thing, and that it would have been more honourable if he had stood by his colleagues instead of letting them down at this critical moment. It was perfectly clear that there had been either gross misrepresentation or gross mismanagement—[a Voice: Both]—perhaps both, and his impression was that Mr. Rawson was responsible for both. It was a matter which required to be gone into thoroughly. What they wanted now to do was to put a stop to the loss now being made of not less than £100 a day. In his opinion, in the report before them they had excellent advice, and under proper conditions they might be able to make a handsome profit. He concluded by recommending them to go into voluntary liquidation.

It being the evident sense of the meeting that voluntary liquidation was the best course to pursue,

A long discussion ensued as to the precise terms of the resolution to be submitted so that the property meanwhile might be properly protected, and eventually,

Mr. SEABORN moved:

"That we, the undersigned shareholders of the Elmore French Patent Copper Depositing Company (Limited), hereby signify our desire that the Company should be voluntarily wound up, with a view to reconstruction under the supervision of the Court on the following grounds:—That the Company cannot, by reason of its liabilities, carry on its business, and that the Company is unable to pay its debts, and that Messrs. Harries, Wilkinson and Raikes, solicitors, be instructed to institute the necessary steps for winding up accordingly, and that we will attend the necessary meetings with the view of obtaining the necessary resolution, and that the Directors be called upon to call a meeting for the purpose on April 5th next."

A SHAREHOLDER seconded the motion, which was carried unanimously, and a vote of thanks to the Chairman terminated the proceedings.

Notting Hill Electric Lighting Company (Limited).

The following is the Directors' report, to be presented at the sixth ordinary general meeting of shareholders, to be held at the Central Station, Bulmer-place, High-street, Notting Hill Gate, W., on Monday next, the 27th inst., at 5:30 p.m.:—

The expenditure on capital account at the date of the last balance-sheet amounted to £67,845. 13s. During the year a further sum of £9,054. 14s. 7d. had been expended, bringing up the total to £76,900. 7s. 7d. Out of this total £7,110. 7s. was expended on mains, and £1,535. 3s. 4d. on additional machinery, rendered necessary by the increase in the area supplied.

As mentioned in the last report, the Directors entered into a contract with Messrs. Crompton and Co. (Limited) to extend the mains southward into the Phillimore district, and this work has been carried out at a cost of about £6,500, under the supervision of Mr. Joseph Crookes, to the entire satisfaction of the Directors. Smaller extensions have been made by the Company's own workmen under the supervision of the resident engineer.

At meetings held on May 13th and 31st, 1892, powers were taken to issue the balance of the capital, amounting to £29,980, in ordinary preference shares, bearing 6 per cent. cumulative dividend. Of this amount £7,960 were issued up to December 31st, the proceeds of which were employed towards the capital expenditure above mentioned.

The revenue for the year, which shows a satisfactory increase, amounted to £3,513. 12s. 5d., the revenue from sale of current being £2,518. 17s. 1d. for the twelve months, as against £999. 10s. 6d. for the previous seven months. The number of houses supplied has increased from 77 to 124, and the number of lights from 6,056 to 9,438. There is every reason to expect a considerable increase for the current year. The mains at present run past and opposite to 886 houses which are not yet taking current.

The Directors are pleased to be able to report that the machinery and plant at central station, as well as the mains, are in excellent order, and that universal satisfaction is expressed with the steadiness and quality of the light.

As the profits of the Company depend, after a certain amount of output is reached, upon the amount of annual revenue per lamp, with a view to encourage development in this direction, a sliding system of rebates has been instituted, by means of which the charge for current to consumers whose lamps yield a gross revenue of upwards of 10s. a year will be proportionately reduced, the minimum rate being fixed at 6d. a unit.

The profit for the year amounts to £112. 6s. 1d., which compares with the loss of £554. 18s. 6d. (reduced by the return and postponement of undrawn Directors' fees to £304. 18s. 6d.) for the previous seven months. Having now turned the corner, there is reason to hope that the Company will soon yield to its proprietors a return on their investment.

In view of the slender amount of net revenue now available, the Directors have refrained from drawing any fees during the past year, and do not intend to draw any during the year 1893, until after the results of the working have been ascertained and the report presented to the shareholders; with a view to further lighten the prospective burdens of the Company, they have renounced 50 per cent. of their fees up to and including the end of the year 1893. In consequence of this no charge for Directors' fees appears in the accounts.

The Directors who retire are Messrs. W. Crookes and S. Waters, and, being eligible, they offer themselves for re-election.

The auditors, Messrs. Deloitte, Dever, Griffiths and Co., retire and, being eligible, offer themselves for re-election. They have expressed their willingness, in view of the Company's position, to accept a fee of £15. 15s.

NEW COMPANIES, STATUTORY RETURNS, &c.

[*In addition to the information given under this heading, detailed particulars of many of the Companies whose returns appear below wil be found in* "THE ELECTRICIAN" ELECTRICAL TRADES' DIRECTORY AND HANDBOOK, 1893, pages 320-348, *&c., &c.*]

EBENEZER TIMMINS AND SONS (LIMITED).—This Company has been registered with a capital of £20,000 in £20 shares, to acquire and carry on the business of civil mechanical, electrical, and general engineers, iron and brass founders, metal workers, metallurgists, &c., at Runcorn.

ENGLISH ELECTRIC CARBON COMPANY (LIMITED).—This Company was registered on March 18th, with a capital of £10,000 in £10 shares, to erect and establish works for the manufacture of electric light and other carbons, at The Smelt, near Brymbo, Denbighshire. The first Directors are John H. Darby, Sir Henry B. Robertson, William Darby, and Emil Mahla.

OSWESTRY ELECTRIC LIGHTING AND POWER COMPANY (LIMITED).—This Company was registered on March 2nd with a capital of £10,000 in £1 shares, to carry on at Oswestry, Salop, the business of an electrical supply company in all its branches, to generate, produce, accumulate, transmit, distribute and supply electricity, magnetism, or other similar agency; and to sell, manufacture, construct, erect, all kinds of electrical machinery, apparatus, and fittings. The subscribers (with two shares each) are—W. W. Coulson, Fernlea, Victoria-road; E. M. Gardner, 1, Clarendon-villas, Queen's-road; Robert E. Hughes, 15, The Cross; F. F. Leaver, 32, Church-street; A. Minshall, 18, Salop-road; John Minshall, and R. Taylor, Porkington-terrace (all of Oswestry).

OTIS ELEVATOR COMPANY (LIMITED).—This Company was registered on March 20th, with a capital of £50,000, in £10 shares, to adopt and carry into effect the following agreements (1) dated March 13, 1893, between the American Elevator Company and Joseph Cecil Bull (for this Company), for the sale to the Company of the goodwill of the business of manufacturers of and dealers in hydraulic, electric, and steam elevators, and other machinery, carried on by the American Elevator Company in Europe, Asia, and Africa, and of all the inventions, letters patent and other patent rights owned by the said American company; (2), dated March 7, 1893, between Otis Brothers and J. Cecil Bull (for the Company), with reference to improvements in the said inventions; and (3), dated March 13, 1893, between the Brush Electrical Engineering Company (Limited) and J. Cecil Bull (for the Company), for the manufacture by the Brush Company of the said elevators and other machinery, and to carry on in Europe, Asia, and Africa the business of manufacturers of and dealers in hydraulic, electric, and steam elevators, lifts, and other machinery, mechanical engineers, electrical engineers, &c. The first Directors are William A. Gibson, Norman S. Russell, Edward Woods, Henry Sherley Price, and Robert H. Thorpe.

PRINTING TELEGRAPH AND CONSTRUCTION COMPANY OF THE AGENCE HAVAS (LIMITED).—This Company was registered on March 17th, with a capital of £115,000, divided into 23,000 shares of £5 each. The objects are: to acquire the right to use and vend in France and to grant licences for the using and vending, of all or any of the inventions relating to printing telegraphs or improvements in the same, and to carry on in France, the business of transmitting the news of the day to subscribers, and to buy, sell and deal in all things incidental to improvements in telegraphy in France.

MISCELLANEOUS.—B. S. ROBERTS AND CO. (LIMITED), mechanical and electrical engineers. Capital, £2,000, in £5 shares.——BATES PATENTS SYNDICATE (LIMITED), manufacturers of high grade steel, mechanical, and electrical engineers. &c. Capital, £13,200, in £5 shares.——FOWLER'S ENGINEERING COMPANY (LIMITED), mechanical and electrical engineers, machine and engineering tool makers. Capital, £2,000, in £5 shares.——GEORGE JONES (LIMITED), iron and brass founders and mechanical and electrical engineers. Capital, £10,000, in £5 shares.

CHATHAM, ROCHESTER, AND DISTRICT ELECTRIC LIGHTING COMPANY (LIMITED).—The annual return of this Company, made up to December 29, 1892, has been filed. Out of a nominal capital of £50,000, in £5 shares, 3,690 shares have been taken up, of which 1,663 have been issued as fully paid. Upon 2,000 of the remaining shares the full amount has been called, while the 27 others have had £1 per share called. The calls paid amount to £10,025, leaving £2 unpaid. Mr. Henry Jasper, of High-street, Chatham, holds 2,907 shares. An agreement, dated January

Hosted by Google

21st last, with the said Henry Jasper (referred to as the contractor) states that it had been agreed between the contractor and the Company that certain works should be erected by the former for the sum of £16,630 in fully-paid shares, one-half payable before commencing and the other on completion of the works, and that the 1,663 fully-paid £5 shares had been allotted, and that as the Company were desirous of obtaining further plant, and of constructing further works, which the contractor had undertaken to do for £2,000 in fully-paid shares, it was agreed to allot to the contractor 400 shares fully paid. The works referred to are:—To put in a Marshall 195 I.H.P. engine; to substitute a 100 kilowatt Brush alternator for a 50 kilowatt Brush alternator; and to substitute ropes for belts for the 100 kilowatt machine

COLLIER-MARR TELEPHONE AND ELECTRICAL MANUFACTURING COMPANY (LIMITED).—The statutory return of this Company, made up to December 23, 1892, has been filed. Out of a nominal capital of £100,000, in £10 shares, 1,015 shares have been taken up. Upon these shares a call of £7. 10s. has been made, resulting in the payment of £5,110, and leaving £2,552. 10s. in arrears. An agreement, dated December 31, 1892, between the Collier Audible Telephone Syndicate (Limited), Godefroi D. Ingall, and the above Company, states that by previous agreements it had been agreed that the syndicate should sell to the Company all their property, patents, goodwill, business, &c., for £51,500 payable, £400 in cash and the rest in shares, and whereas a sum of £1,500 had been utilised for other purposes, it is therefore agreed that the remainder of the purchase consideration, viz., £46,000, shall be satisfied by the allotment of 4,600 fully-paid shares to certain persons named in a schedule to the agreement.

CUBA SUBMARINE TELEGRAPH COMPANY (LIMITED).—The annual return of this Company, which was made up on March 8th, has been filed. The whole capital of £220,000, divided into 16,000 ordinary and 6,000 preference shares of £10 each has been taken up, and the full amount called and paid.

DOUGLAS PATENT BLOCK AND ELECTRIC METER COMPANY (LIMITED)—This Company has been dissolved. The Company was registered in November, 1888, with a capital of £10,000, in £10 shares, to carry on the business of manufacturers of a patent detached pendulum and other clocks, and of meters for the measurement of electric currents, at Vyse-street, Birmingham. In reply to inquiries in 1891 the secretary stated that the business of the Company had been sold to the Electric Meter Company (Limited).

ELECTRICITY SUPPLY CORPORATION (LIMITED).—The annual return, made up to April 27, 1892, has recently been filed, and shows that at the time of making up 718 shares out of a total of 30,000 shares of £5 each, had been taken up, the full amount called, and all calls (£3,590) paid. The return for 1893, a public issue of capital having been made during the interval, made up to March 3, 1893, and filed at the same time as the foregoing return, shows that 16,556 shares had been taken up, the full amount called, and £82,780 paid in respect of calls.

L'ELECTROLYSE.—A Company, with this title, and a capital of 250,000fr., has been formed in Paris to exploit the Perreur-Lloyd system of electrolytic separation of metals.

GALLOWAYS (LIMITED).—The annual return of this Company, made up to March 3, 1893, has been filed. Out of a nominal capital of £250,000, in £100 shares, 2,108 shares have been taken up. On these the full amounts have been called, and all calls (£210,800) have been paid.

HENLEY TELEGRAPH AND ELECTRIC CONSTRUCTION COMPANY (LIMITED) (in Liquidation).—A meeting is to be held at 6, Clement's lane, London, E.C., on April 14th, at 12, to receive an account of the winding-up.

SHIPPEY BROTHERS (LIMITED).—The annual return of this Company, made up to December 31, 1892, has been filed. The Company was registered on December 30, 1887, with a capital of £30,000, in £5 shares. At the time of making up, 2,412 shares were taken up, of which 1,800 were issued as fully paid. Upon the remaining 612 shares the full amounts have been called, and all calls (£3,060) paid.

SUNBEAM LAMP COMPANY (LIMITED).—An agreement dated August 19, 1892, and recently filed, between the Company, Mrs. Margaret Clarke, Thomas Bowden, Abel H. Chapman, and John B. Furneaux, states that whereas legal proceedings had compelled the Company to cease manufacturing incandescent electric lamps until the expiry in November, 1893, of the patents of the Edison and Swan United Electric Company (Limited), and whereas the Company deemed it expedient to erect new works for the manufacture of such lamps on the expiry of the said patents, it was therefore agreed that the said Mrs. M. Clarke and Thomas Bowden should surrender 554 fully paid shares, that Abel H. Chapman should surrender a similar number, and that John B. Furneaux should surrender 35 fully paid shares, making a total of 1,143 shares surrendered; that the Directors should be at liberty to allot such surrendered shares, and also 287 original shares then unissued; that until a dividend of 5 per cent. had been paid in any one year to the other shareholders, the parties to the agreement should not be entitled to a dividend on their fully paid shares, but after such dividend had been paid they should be entitled to a similar one on their fully paid shares, and share equally with the other shareholders in any surplus profits; and that the Company should be authorised to issue mortgage debentures (out of a total of £3,000), bearing interest at 5 per cent., in payment for land and buildings required. The annual return of this Company, made up to February 8, 1893, has been filed; 1,595 shares had been taken, of which 857 had been issued as fully paid. Upon 213 shares the full amount had been called, and upon the remaining 525 shares £1 per share had been called, resulting in the payment of £2,625, leaving £30 in arrears.

CITY NOTES, &c.

ARCAS PLATING COMPANY (LIMITED).—The statutory general meeting of this Company was held on Monday at Winchester House, Old Broad-street, E.C. The Chairman (Mr. E. Wolseley) said that they had got a most valuable patent, and that as soon as they extended the works, as they proposed to do immediately, they would be able to meet after a few months' time with very satisfactory results to all. He might mention one thing, that the London Metallurgical Company, from whom they purchased this patent, had behaved in a most generous fashion to the Arcas Company. It was quite uncalled for, because they paid a large sum of money in shares for this patent—the English patent of the Arcas plating; but the London Metallurgical Company had given to them, without any charge of any sort or kind, the American patent, and, as they were aware, in America electro-plating is much more extensively used than it is in this country. They were going to exhibit in the Chicago Exhibition, and he hoped to be able to sell during the course of the year the American patent for a very considerable amount of money. The whole of the £15,000 working capital had been subscribed.

CITY AND SOUTH LONDON RAILWAY COMPANY (LIMITED).—The traffic receipts for the week ended March 19th were £880, as against £896 for the corresponding period of last year, being a decrease of £16. The total receipts for half-year amount to £10,411 against £9,404 in the corresponding period of 1892, being an increase of £1,007.

COMMERCIAL CABLE COMPANY.—This Company proposes to offer to existing shareholders 19,290 new shares at par, in order to provide funds for the laying of the third cable.

EASTERN TELEGRAPH COMPANY (LIMITED).—This Company announces the payment on April 14th next of interest of 3s. per share, less income-tax, being at the rate of 6 per cent. per annum on the preference shares of the Company for the quarter ending March 31st, and the usual interim dividend of 2s. 6d. per share on the ordinary shares, free of income-tax, in respect of profits for the quarter ended December 31st last. The register of transfers will be closed from April 7th to 14th, both days inclusive.
